

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

"Oh look thou largely with lenient eyes
On what so beside thee creeps and clings,
For the possible glory that underlies
The passing phase of the meanest things."
—*Mrs. Whitney.*

PREFACE TO "INSECT LIVES."

GALL-NUTS ("OAK APPLE").
HOME OF THE "CYNIPS CONFLUENS."

HOW shall we interest young people?
How shall we *most* interest them?
How shall we *best* interest them?

You give to your boy a glass ball. It is clear and beautiful. He can amuse himself with it. How? Not by studying it, but by rolling or catching it. Tell him to put the

ball under a glass cover and watch it. Tell him to wait and look again and see what he will find. "Nothing," he says, "but a ball." He is right. Man made it, and all the beauty it will ever have it has now. Give him a microscope. What does he see? A little coarser texture, perhaps a flaw, a bubble of confined air, but only the same glass ball. Go with him to the forest. Pick from an oak branch a plain brown ball. Is this *only* a ball? Put it under a glass. Look again and you will find it more than a ball. It is a home. The doors will soon open and the family disperse. Watch. There goes one in full dress out on an early promenade. With what ease and grace it walks up and down its prison of glass. Another follows. There is a large family for so small a house. Who built it? Was it cast in a mould by a man? God made it, and all the beauty it has is not seen at first. Take the microscope. No roughness is revealed, no flaw, but exquisite beauty and finish in every part of the house, in every part of each perfect inmate. Suppose a boy could buy a glass ball that would develop such wonderful secrets. What merchant could supply the market? Aladdin's lamp would be at a discount.

You give your girl a silk "beechnut-box." Some of them will know what I mean: a three-sided box, made of card-board and covered and lined with silk, such as only grandmothers can probably make now. She looks at it. It seems solid. Press it and it opens. One side has been left without being closed. What can she do with it? It is better than a ball. It will hold something. She can use it. But the box itself, what will it come to? Tell her to put the box under a glass and see what it will get to be. She will laugh and tell you, "only a box." All there is to it she sees at once. Try the microscope. Only a little coarser silk.

Here is a green "beechnut-box" I have found on a walnut leaf. It is very small—no larger than a beechnut and looking much like a green one. Is it a box? Let us try the microscope. It is embroidered on the sides and back. There are small patterns in diamonds in brown and drab. While you look it moves. Put it under a glass and watch. Is it a home? Put a bit of walnut leaf by it. What is that moving just under one of the pointed ends? It is a head. The leaf begins to disappear, the owner of the box, the *Limacodes scapha*, is taking his breakfast.

Which will you prefer, the glass ball or the round, brown house, the silk box or the curious living thing that has surprised you and holds in reserve a still greater surprise?

It is with the hope of getting this question answered in favor of living balls and boxes, of getting the key into the hand and getting the heart ready and anxious to unlock the many sources of beauty and interest which God has placed all about us in nature, that this little volume of "Insect Lives" has been written. That we may learn that while "it is the glory of God to conceal a thing," He is not only willing we should search out these hidden wonders, but will Himself be glad in our new-found delight in them.

EASTON, PA., Sept. 26, 1879.

LIMACODES SCAPHA.

("BEECHNUT-BOX.")

AMONG THE MOTHS AND BUTTERFLIES.

I.

BORN IN PRISON.

I AM only a day old ! I wonder if every butterfly comes into the world to find such queer things about him ? I was born in prison. I can see right through my walls ; but I can't find any door. Right below me (for I have climbed up the wall) lies a queer-looking, empty box. It is clear, and a pale green. It is all in one piece, only a little slit in the top. I wonder what came out of it. Close by it there is another green box, long and narrow, but not empty, and no slit in the top. I wonder what is in it. Near it is a smooth, green caterpillar, crawling on the edge of a bit of cabbage leaf. I'm afraid that bright light has hurt my eyes. It was just outside of my prison wall, and bright as the sun. The first thing I remember, even before

my wings had opened wide, or I was half through stretching my feet to see if I could use them in climbing, there was a great eye looking at me. Something round was before it, with a handle. I suppose it was a quizzing-glass to see what I was about. I heard somebody say, "Oh! oh!" twice, just as if they wondered I was here. Then they held the great bright light close to the wall, till my eyes were dazzled. I don't like this prison.

FIG. 2.
CABBAGE BUTTERFLY AND CATERPILLAR.

FIG 3.
CHRYsalis.

It is n't worth while to fly about. It seems as if I ought to have more room. There must be something inside that green box. It moves! I saw it half tip over then, all of itself. I believe that caterpillar is afraid of it. He creeps off slowly toward the wall. How smooth and green he is! How his rings move when he crawls! Now he has gone up

the wall. He has stopped near the roof. How he throws his head from side to side! He is growing broader! He looks just as if he was turning into one of these green boxes! How that box shakes! There, I see it begin to open! There is a slit coming in the back! Something peeps out! A butterfly's head, I declare! Here it comes—two long feelers, two short ones! Four wings, two round spots on each of the upper pair, and none on the other two. Dressed just like me. I wonder why it hid away in that box?

First Butterfly.—“What made you hide in that green box?”

Second Butterfly.—“What box? I have n't hid anywhere. I don't know what box you mean.”

First Butterfly.—“That one. You just crawled out of it. I saw you.”

Second Butterfly.—“That 's the first I knew of it. There are *two* boxes, just alike. *Both* empty. May be you were hid in the other!”

First Butterfly.—“Ho! There goes up our prison wall! That 's the big hand that held the bright light. How good the air feels! Now for a chance to try our wings! Away we go!”

II.

THE GREEN HOUSE WITH GOLD NAILS.

THERE is a very pretty caterpillar which lives upon the common milk-weed, or *Asclepias*, which grows by the roadside, with pinkish clusters of flowers in summer, and curious bird-shaped pods in the fall. This caterpillar (whose name is *Danaïs archippus*—we might call him Archie, for short) is very pretty, and the butterfly is handsome; but the crowning beauty of all is the chrysalis. It looks like a little green house, put together with gold nails. It is somewhat of the shape and size of a long, delicate pea-green acorn, and has a row of dots half-way around what would be the saucer of the acorn, with others about the size of a pin's head on different parts of the chrysalis, and you will say they are not like gold, but are real gold itself.

The caterpillar, when full-grown, is about two inches long. It is cylindrical, and hand-

somely marked when mature, with narrow alternating bands of black, white, and lemon-yellow (Fig 4). These bands are not entirely even,

FIG. 4. DANAIS CATERPILLAR.

and occasionally run into each other. On the top of the second ring, or segment, are two slender, black, thread-like horns, and on a hind ring two more, not quite so long as those near the head. You can find it almost any day in July or August, if you look closely, on the underside of the broad ovate-elliptical leaves of the milk-weed. When this caterpillar first leaves its conical, reticulated egg (Fig. 5, which is always found on the under side of the leaf, a miniature hanging basket, first yellow and then gray, as it develops), it is perfectly cylindrical, and of nearly the same size throughout, and only twelve

FIG. 5.
AN EGG, MAGNIFIED.

one-hundredths of an inch in length. In this, its *first coat*, it is a pale, greenish white, and the horns (front and back) are mere conical points, and it is covered with little black hairs or bristles, from minute warts on the back and sides. The breathing holes, or *stigmata*, show on each side, marked by a plain, narrow band. In the next coat, which it puts on in a few days, the black stripes appear, and also faint lines of white and yellow, and the horns are longer. The third and last coat (before the final change to the chrysalis) is much the same, except that all the colors are brighter. The horns are shed with the skin, new ones having been formed beneath to take their place. These have been so carefully folded away that at first they scarcely appear; but they are soon developed, or uncurled, and unbend so suddenly as almost to surprise one.

FIG. 6.

When the caterpillar is ready to make its change into the chrysalis, it spins a little tuft or button of silk to the under side of the leaf (or the box-cover, if in prison), into which it fastens its hind legs, by their little hooks, then lets go the hold of its other legs,

and hangs, head downward, with the body curved, as in Fig. 6.

In this position it remains about twenty-four hours when the marvellous change is wrought—the coat thrown off and the chrysalis (Fig. 7) developed.

It was the accidental finding of this chrysalis, attached to a spray of wild carrot, that led me to study this particular species. It was a secret to me—this beautiful green-and-gold house. It held something. What, I must know! Cutting the stem of the carrot, I brought the treasure carefully into the house, covered it with a tumbler, and for a week it remained just the same. Then the green began to turn to a light purple, and

FIG. 7.
DANAID CHRYSALIS.

FIG. 8. FRONT VIEW.

FIG. 9. BACK VIEW.

lines began to show through the clear case. The front showed lines like a curtain, parted and folded back each way, like drapery to the

bottom, as shown in Fig. 8. The back was curiously marked off, and looked like Fig. 9. The whole gradually took on a very dark purple hue, and I hoped to see it open and give up its treasure. But though I watched very carefully, it stole a march on me, and one morning I found its secret disclosed and fluttering below the empty chrysalis, now but a clear, rent tissue, with here and there a pale gold dot.

The butterfly is handsome and quite large (more than three inches across when the wings are spread), but not quite so beautiful as you would infer from his elegant house. He is of a rich tawny orange, bordered with velvety black on the upper side, and a lighter nankeen yellow below; and has a large velvety black head, spotted with white.

As I did not know how large he would be, nor when he would come out—for he did not invite me, as I said, to his “opening,”—I had not given him a glass roomy enough for his wings to expand entirely at the first, as they must, or remain imperfect. So afterward, although he had the liberty of the whole room, he walked about with one wing folded back over his shoulder, like a lady’s opera-cloak. But I kept him, and, learning that he came from the

milk-weed caterpillar, I went in quest of one. I was fortunate enough to find five in one search—three on one milk-weed, and two on another. I put them in a glass fernery, about one foot long and ten inches high, and fed them with fresh milk-weed leaves daily. Soon they mounted, one after another, to the top, and began to work on the under side of the glass cover. My curiosity was on the alert to see how each would build his green house. I had seen cocoons of various kinds spun; but the glass-smooth chrysalis could not be spun. Oh, no! It was altogether too nice work to be done in sight. There was no sound of hammer or sight of tools. It was all polished and painted and ready—and lo! the inner layers of the caterpillar's skin had been the workshop, and the outer skin was taken down and discarded, like worthless scaffolding, when the green-and-gold house was ready. Pretty soon there were five of these houses hanging from the glass roof, side by side; and now there are five empty homes still clinging by the little shiny black twist that fastens them firmly to the glass, and five handsome great butterflies, like the one shown in Fig. 10. Only one of all these did I see break the shell and come out, and that only by the most

diligent watching. The butterfly was packed, head downward, at the bottom of the chrysalis—wonderfully packed, as all will admit who see him emerge, to shake himself out into something five or six times as wide, a beautiful uncramped butterfly.

FIG. 10. *DANAUS ARCHIPPUS.*

After seeing them brighten a bouquet, and watching them eat with their long spiral tongues from a little bed of moss sprinkled with sweetened water, I let them take a nap under a tumbler with a little pillow of chloroformed cotton, and, unmarred even by a pin, they were ready to be laid away in a glass-covered box in their long, dreamless sleep.

It has been said by some entomologists that each plant is visited by about five different insects. This year (1877) I have searched in vain on the milk-weed for the large, handsome caterpillar of the *Danaïis archippus*. That there must have been a few the occasional presence of the Danaïis butterfly has proved. Two were seen in Massachusetts, flitting gayly past me as if in mockery of a long and futile search I had just made for the caterpillar among a whole tract of milk-weed; one in Brooklyn, and one or two in Pennsylvania, but they were exceedingly rare. The eggs were probably destroyed by spiders and other insects, but why to so much greater extent than the previous year is not so readily explained.

The only caterpillar (and that very abundant) which seems to have lived upon milk-weed this year, and found upon the same spot where the Danaïis caterpillars were so readily obtained last year—sometimes half a dozen upon one plant,—is a small one in comparison to that of the Danaïis, of a soft, woolly appearance, orange-red in color, and about an inch in length, with hairs thickly set in starry clusters about each fleshy ring. Three of these abundant orange-red caterpillars have

gone into shiny-brown chrysalids and come out, after a three weeks' sleep, into lavender-colored moths, perhaps an inch and a half across the expanded wings, the wings edged with a narrow orange border. They were "travelled" caterpillars, going in a box as chrysalids from Pennsylvania to Massachusetts, coming out there, and travelling back as quietly as if long journeys were a matter of course. A second set of caterpillars of the same kind appeared in August, some of which are now (September) in their chrysalid homes. They made from their woolly, downy hairs (more soft than those of any other caterpillar I have seen) a soft cocoon like loose felt, and these four have gone up in pairs, two chrysalids in each thin cocoon. This little lavender moth is neat and quite pretty, but not to be compared for beauty to the *Danais archippus*.

It has always been with a feeling akin to sadness that I have seen the walls of the beautiful home of the *Danais* butterfly break, and its beauty vanish, even for the release of the scarcely less lovely winged creature that sails off, regardless of its shattered home. It is not so strange after all that it should be able to leave it without regret, when one considers that no *Danais* butterfly has ever seen

the handsome house it lived in! For before it can escape the walls grow very thin, the gold nails vanish, and when the rich brown and orange-yellow butterfly steps out so airily, there is nothing left but a clear bit of broken glass-like material to hint of the once exquisite green and gold home.

But *now* the butterflies can see what sort of a home they had, if not their own, those of their neighbors, precisely like them. Here are green houses, as perfect after more than their usual fortnight has gone by as when first made. The gold nails still bright, and the walls intact. The butterfly has been requested to *stay at home*; and if he had any objections, they vanished so soon as his house was placed in that safest of all places, the cyanide jar!¹

Five of these houses (a very handsome block) I have now before me (September, 1889), in a row, to remain permanently; with the satisfaction of knowing that the imprisoned occupant can never realize what it has sacrificed for my pleasure, in thus *staying at home*.

Making a collection of the *eggs* of butterflies

¹ The arresting of the transformation of the *Danais*, by placing the chrysalis for some hours in the cyanide jar used for killing the perfect insect, was a new thought to me, which experiment proved a success; and which may open the way for the preservation of all chrysalids.

and moths (or of any insects, in fact) is only second in interest to the collecting of the perfect insects themselves. And this is far more easy than one would suppose. Looking on the under side of a forest leaf, or of a plant or vine near your door, will often reveal clusters of eggs, that one not "on the search" would never dream of being there. The last summer I secured more than two dozen eggs of the *Danaïs archippus* by searching the leaves of the milk-weed; never finding but one on a leaf, and that one always on the under side of the leaf, and so small as to escape notice but by a careful and practised eye. The egg is of a light color, and about as large as a "period" in the book you are reading. On the 6th of August last (1889), I watched one of these tiny eggs open, and I shall never forget the pleasure I experienced as I saw the little prisoner make a minute hole in the egg and put out a jetty black head, turning it this way and that, before he left his prison, as much as to say: "I wonder what sort of a world it is that I am about to step into!" He was not long in deciding the question "Is life worth living?" and bravely stepped forth to try it. I noted this as the greatest amount of intelligence in the smallest

compass that it had ever been my good-fortune to witness! He tried "life" and found it, with a plentiful supply of milk-weed, well worth living, went through all his changes till he entered his royal castle of gold, and came forth to a higher life, which, as long as it lasted, was only one of unmixed enjoyment.

On another leaf, from the maple tree, I espied seventeen glassy, bead-like eggs, and from them came seventeen of the beautiful Rosy Dryocampas, now waiting in their notched chrysalids their time of winged freedom.

Upon a maple leaf on the tree, and upon a pretty high bough, I espied, last fall (September, 1889), in walking by, what I at once divined to be the egg of a Polyphemus moth. Securing it, in spite of the smile of the friend with me, who thought it impossible to see an insect's egg of any sort at that distance, much less to determine its character, I am rewarded whenever I look at the fine large Polyphemus cocoon, now almost ready for its spring opening. Other clusters of eggs, larger in numbers than those named of the Dryocampa and Danais were found, some of most exquisite finish and beauty. The idea given above about "*jarring* the chrysalids," was transferred to the *eggs*, and by placing such a

portion of any cluster found as I did not wish to have *try life*, in the cyanide jar, I found them ready to place in a box in my insect-egg collection.

FIG. II.

III.

TWO FRONT DOORS, AND WHAT WAS BEHIND THEM.

A BUTTERFLY in March! Velvety black, with wings bordered with a double row of yellow spots, and the hinder wings tailed, having also the added ornament of seven blue spots (a nebula of dotted blue points, with a frosted silvery sheen marking each spot). He is the *Papilio asterias* (Fig. 13). You have seen him in May, June, or July, hovering over a bed of phlox or other sweet flowers; but unless you caught him "in the bud," or, of course, when a caterpillar, you would not have him in the middle of March.

FIG. 12. CATERPILLAR OF PAPILIO ASTERIAS.

The sole occupant of a glass fernery, sipping from sugar-sprinkled moss with his long, un-

coiled tongue, he seems quite at home, and sees nothing of the snow now whitening every branch and tiny shrub—knows nothing of the “April-fool,” which, as Susan Coolidge says, spring throws to the flowers outside—the daring crocus and daffodil. With his moss, and some fresh snowdrops in a vase, standing in his glass house for dessert—an extra drop of sweetened water in their pure cups—he is monarch of his little world.

As a caterpillar, he was handsome. At first a tiny black caterpillar, with a white stripe running through the centre of the body and across the tail, and covered with some small black dots or points. The next coat has but one white stripe across the middle, on the sixth and seventh rings, with orange spots beneath the black points, two white spots on his first ring, and a row of white spots on each side. Then at last he has a rich coat, striped with black and dark green, and ornamented with deep yellow spots (Fig. 12). But his chrysalis is quite plain, with nothing of the exquisite beauty of the green- and- gold house of the Danais. But when he leaves his shell, coming out by the narrowest possible front door, so that you must look sharp to see the thread-like opening, then he is much handsomer than the

Danaïd butterfly. So, many people, living in plain tabernacles, and sometimes regarded homely by others, have something within, waiting to give great surprise, when they shall have escaped, through a narrow door, into a world of wonderful light and beauty !

The *Papilio asterias* is very fond, in his caterpillar form, of the wild carrot, or garden

FIG. 13. PAPILIO ASTERIAS.

carrot, parsley, or celery, and any of the warm, aromatic plants, as anise, caraway, and dill.

This March butterfly, as a caterpillar, was eating his delicate carrot leaves and seeds last September at the same time with the Danaïd caterpillar, and as we brought them fresh leaves, day after day, and watched them go into their queer little houses at the same time, we did not know then but they would have

their "opening" also, together. But while the *Danaïd* was ready to come out in a fortnight, or three weeks, the *Asterias* slept on until March—six months under his glass roof, without moving a hair's breadth, until he was out trying his new wings yesterday morning. Some other kinds of chrysalids have kept him company all this time, except that they have moved a little, and sometimes a good deal (when touched with a pencil, or slightly blown upon), showing the life within; but not a particle—watch him never so closely—moves

FIG. 14.

the *Asterias*. There were six chrysalids of this one kind under separate glasses; all of which were taken as caterpillars, and each of which I had watched go into his separate

house. It is not a cocoon, woven as some are of their own hairs, or spun from some hidden substance through a spinneret; but like the Danaids' it is formed under the caterpillar skin, and when he is suspended as a caterpillar, with a silken thread holding him about the body, as shown in the picture (Fig. 15), he drops off the entire skin, and it remains, as seen, beside his chrysalis, which is pale and nondescript in color, knobbed with many little round protuberances, giving it a curious rather than pretty appearance.

FIG. 15.

When one was out, the next thing was to look at the others, when lo! a most surprising revelation! Another chrysalis was empty, but the *front door* was very different! Instead of a crack, a thread wide and half an inch long, in the upper part of the back (Fig. 14, 1)—(the narrow black line in the chrysalis shows the butterfly's door), there was in the side (marked O in the picture of the chrysalis, and only belonging there to show this second front door) a perfectly round hole (Fig. 14, 2), the size of a pea; and trying his new wings (four narrow, glossy, blue-black ones), was something more unlike the butterfly than was the circular

door he came out of unlike the narrow door of the *Asterias*. Looking something like a saw-fly, and more like a wasp, it was a large ichneumon fly. The parent ichneumon, having stung the caterpillar and deposited the egg, the ichneumon was safe in his provided chrysalis home, when he woke up to a sense of his privileges, and not only appropriated the house of the *Asterias*, but literally lived on the occu-

FIG. 16. ICHNEUMON FLY.

pant, eating him up and then making his own way into the world, leaving the chrysalis entirely empty, and quite whole, with the exception of the round door. His head and slender body, antennæ, and six feet, are all an ochre yellow. The eyes are large, jetty black, and oval-shaped, and back of them, on the top of the head, are three round, black beads, in a triangular position. His body is joined to his head and shoulders by a pedicel, so long and

slender that he is able to work from it like a pivot, in all directions, giving as fine specimens of gymnastic operations as one often sees.

His veined, clear wings are exquisitely glossy, and he polishes their steel blue till it burns like a mirror. He has the vanity of a Beau Brummel, judging by the great pains he hourly takes with his entire toilet. Grasping both his long trembling antennæ at once, and smoothing them out again, as a philosopher would stroke his beard, nothing is left on one of their thirty-five segments large enough for a microscope to reveal. Then his wings and six legs go through the same operation, and he is ready for a fresh supply of sugared sweets. But alas, his mouth ! If he had claim to beauty in every other particular, one good look at this remarkable feature in a mirror would secure his humility for ever. An hour's close study with the microscope reveals no trace of beauty about it ! The most curious transformations do no good in redeeming its unmistakable homeliness. There are three projections from it—impossible to describe—two seem like short, curved legs, with which it clasps its throat, and the centre is a curved affair something like the letter V. It is very much like the mouth of a wasp, but in

such constant motion that one cannot guess at its exact shape or manner of manipulation.

It is well that it is so small that it does not detract from his looks except with the use of a microscope—and so long as he does not know it himself we will allow his vanity to be pardonable.

One such parasite will, however, satisfy us, and we hope only the *narrow* front door will open for the rest of the *Asterias* chrysalids.

IV.

THE EARLY BUTTERFLY.

WALKING up a rocky lane one warm day in the latter part of winter, my attention was called to a large, sombre-looking butterfly, lying flat upon a rock. Any sort

FIG. 17. THE EARLY BUTTERFLY. *VANESSA ANTIOPA*.

of butterfly, so out of season, was worthy of notice, and as this one was very quiet, as if

half asleep, I easily took him up and carried him home with me. He was handsomer upon inspection than at first sight I had imagined. The wings, though grave in color, were really a rich purple brown, with a broad margin of light yellow or buff, and six or seven spots of a lavender color inside of the border on all the wings. He had a queer, pinched-looking head, with sharp features, and furry front feet. I did not know his name, and as he was very restless, and beat constantly against his prison wall, I gave him his liberty. Some months after, on June 5th of the same year, I found on a shrub, in the same rocky lane, a very formidable-looking spine-covered caterpillar (Fig. 18).

FIG. 18. *VANESSA ANTIOPA* CATERPILLAR.

He was black, but dotted with minute irregular white spots, like tiny snow-flakes. There was a broad black line running down the back, interrupted by eight spots of brick-red. Each side, also, was dotted with white spots. There were seven rows of large spines, besides a row of very small but similar ones low down, just over the feet. Each of the

two centre spines on the ten rings were branched, as also the two on the last ring. As these spines were stiff and sharp, and did not lie particularly close to his body, he was treated in a very cautious manner until safe in his glass prison, although I have been told that these caterpillars, and in fact nearly all caterpillars, however formidable they may look, are in fact harmless. The fiercest one I have ever seen, that of the regal walnut moth (*Ceratocampa regalis*), very large, and with horny spines stretched over the head, which when disturbed he shakes in a threatening manner, is said to be perfectly harmless. One would certainly prefer to test this harmlessness when he had thrown off his horns, and, after a smooth, chrysalis life, come out into the beautiful walnut moth.

The caterpillar I had imprisoned did not at first like his confinement at all, and showed a most worthy persistency in attempts to solve the possibilities of escape, walking with entire contempt over the fresh leaves of the willow from which he was taken (and any species of which he will eat), going up and down and across to every corner and joint of the box, until, at last, apparently satisfied that he was secure in his new abode, he wisely accepted

the situation and began such a marvellous course of eating as showed that he had determined, if he must be a prisoner, not to commit suicide by starvation. Leaf after leaf disappeared and new ones were supplied, until, at length, he suddenly stopped eating, and began to weave a little thread and fasten himself securely at right angles with the side of the box, much in the same way as the *Danais* caterpillar. His head is round, large, and flat on the top, resembling the old-fashioned velvet "jockey cap." There is no red spot on the first two rings from the head, but on all the rest; each spot, on close examination, being made of three spots close together in the form of a triangle, in this manner. ∴ Nothing could be much meeker, or in greater contrast to his first eager restlessness and snappishness, than his appearance after he has fastened himself by his hind feet firmly to the glass, with his head downward and bowed forward touching the glass, only a slight movement of the head now and then showing that he is alive. His three pairs of true feet he draws close together like a wedge, in short spasmodic movements, and then slowly opens them again. At last, after a day or more of this suspension, he throws off the caterpillar skin and shakes him-

self into a brownish chrysalis, which operation takes but a few seconds after it has begun. But the chrysalis, which at first is soft and misshapen, has to assume its characteristic form, which it does by contracting and expanding and throwing out a protuberance, until, in about an hour, it has its shape, and its surface becomes hardened and the chrysalis complete.

FIG. 10.
CHRYSALIS
OF VANESSA
ANTIOPA.

This was on the 6th of June, and on the 18th day of the same month the chrysalis opened, and lo ! there was my early winter butterfly, the *Vanessa antiopa*. This one was much fresher and prettier than the one found in February, and this I could well account for when I learned that this butterfly lives often all winter, hiding in some sheltered spot, stupid and almost dormant, but ready for the first sunny day, sometimes enticed from its hiding-place before the snow is quite gone, its wings somewhat worn and faded by its winter's experience. Since then I know it as the earliest butterfly, and am not surprised to see it early in February heralding the spring far in advance of any other.

V.

THROUGH A GLASS CLEARLY.

WE do not like to see a beautiful thing at a disadvantage. When a large cocoon (Fig. 20, yellowish-brown and leaf enwrapped), cut from a spray of wild raspberry, in September, had been watched for over six months, and showed no signs of life within, it was half given up as a useless affair. Inquiring

FIG. 20. POLYPHEMUS COCOON.

scissors, one day in March, stole an entrance into the cocoon by carefully snipping one end, and cutting spirally round an opening which revealed, unharmed, the living chrysalis within

(Fig. 21). It seemed certain—secret as it then was—that from out this brown-ringed casket some beautiful thing was preparing to emerge.

FIG. 21. BACK VIEW.

FIG. 22. FRONT VIEW.

While watching it closely, a month later, one of the vest-like folds on the breast (Fig. 22) slowly began to part, revealing, first, a curious bridge of fringe across the opening. What could this be? The side of the clear-glass box, even, was too much obstruction for the impatient watcher. "I cannot look at this

through a glass darkly," I said, as the lid was removed; and slowly out came this amber fringe, a broad, beautiful antenna, yellow stemmed from base to tip, with ochre-yellow fibres radiating from it in a perfect plume.

The other soon followed. So large, so full, so beautiful antennæ I had not seen before.

Now for the microscope. Ah, the difference between an obstructing and a revealing glass! Between seeing through a glass darkly and through a glass clearly! A richly-colored centre stem, of thirty-one joints, and two filaments to each joint, of exquisite finish and symmetry. Then a little wider parting of the vest (no breaking of the chrysalis), now and then a shiver and a spasmodic movement of the whole chrysalis, with a little further exit—another shiver, another waiting, and in an hour and a half out came a beautiful (but still limp and contracted) Polyphemus moth (Fig. 24).

A pot of hepatica stood ready in the box for him to cling to while expanding his wings, but the slight, fresh stems proving too frail for his weight, the danger of a fall was prevented by putting a stick into the earth beside the hepatica, to which he immediately clung, and gently unfolded his soft-hued ochre wings, bordered with gray, showing two large and elegant eye-spots on the hinder ones, of a deep blue-black, with a transparent oval in them, clear as a bit of inserted mica. In the upper wings were two smaller transparent ovals; a collar, edged with lake color, and two spots of lake-red, edged with black on the edge of the upper wings, completed his beauty. The body, a soft brown ochre, was furry and

FIG. 24. THE POLYPHEMUS MOTH.

feathery as an owl. Large eyes, six short furry dark-brown legs, a softness of blending in color, and a gentleness and grace of motion crowned the whole. Lifting his large wings, his flight was slow and graceful ; no hurried fluttering and wild beating against the glass when a prisoner ; no dashing about the room when at liberty.

If ever a name was a misnomer, it is surely so in his case. Polyphemus, a one-eyed furious giant, a murderer and greedy cannibal, for *him* to give a name to this two-eyed, gentle-natured, and apparently tongueless moth (whom no sweets could tempt), simply because it is large ! As well might he be called the Tower of Babel, Behemoth, Leviathan, or any other great thing of earth or sea. He is, however, not likely himself to apply to the legislature for redress for this grievance.

The inside of this cocoon is finished with the hardness and smoothness of the inside of an almond shell which it closely resembles, except being much larger.

The larva of this moth is described as of a bluish-green color, with a yellowish-brown head, living upon the oak, elm, and lime trees ; the cast-off skin was enclosed in this cocoon. The disposition of the eye-spotted ogre was

well tested in the artist's saloon. No philosopher ever showed more patience and dignity under repeated trials at the hands of a photographer than he displayed in the hands of his persecutors, with no knowledge of the cause to stimulate his vanity and inspire his courage.

I said the mystery wrapped up in the brown cocoon was "a secret." In studying Natural

FIG. 25. POLYPHEMUS CATERPILLAR.

History we often learn the first part of a lesson last ; sometimes the middle part first ; sometimes it is years after we get part first before we can find part second, even of a short, small lesson. The pages of nature's book are countless, but they are not all numbered, and sometimes we have to stop and wait in a most interesting place. It is all the pleasanter when

we complete the round. After the *Polyphemus* moth had been mounted for months, a beautiful caterpillar was given to me (Fig. 25). He was very large; of a handsome pea-green color, with little points of golden yellow, which, in certain lights, had a beautiful pearly appearance, like frosted silver. There were five or six of these points on each ring. The feet and the head were a light brown, almost exactly the color of an almond shell, and the green V-shaped tail was bordered with a line of darker brown.

He was given to me one afternoon in August, just as I was about to go out for a walk. After admiring him, and noticing carefully his colors and peculiar shape, I said, "I will sketch him on my return." But there are some things which do not wait upon our leisure, and a caterpillar, just ready to retire to private life, is one. So, when I returned to him, two hours after, the only way he could be sketched was with his head and three or four front rings peering out from a well-begun cocoon. He had already attached the leaf (it was a maple, as he was found near a maple tree) to the side of the glass box, and drawn it about him partially, and was working very busily.

My disappointment in his special hurry was relieved, however, by finding, a few days later, and in quite a different locality, another caterpillar of the same kind, which is now before me, clinging to a spray of oak leaves, eating and resting as he chooses, with a sort of elegant leisure. Turning away from a maple leaf, he shows his preference for the oak ; clasping the stem of the leaves firmly with his ten false feet, he moves his brown head silently back and forth, while the leaf melts away before him very steadily. He has the same disposition manifested by the Polyphemus moth, which he anticipates. He never jerks about, when disturbed, or shows the slightest irritation, as do many of the caterpillars, and is so quiet in every movement that you feel sure he is well contented with life as he finds it, with no regrets for the past or speculations about the future. A perfect contrast to him is the little, jerky, impatient caterpillar of the quince, in a box beside him, who, if touched the most lightly, will actually spring up and throw himself entirely over, in the most astonishing manner. Between these extremes, every variety of disposition prevails among them. When at full length, this Polyphemus caterpillar is about three inches long ; but when

hunched up like a half-closed Chinese lantern—as he now lies, eating his oak leaf—he seems but little over an inch in length.

The edge of the first ring, which comes close round like a hood over the brown head, is light lemon yellow, and the upper or second joint of the true feet, and a narrow border above the brown feet, are also yellow. The diagonal side stripes are yellow, also; the spiracles—forming a dash near the centre of each diagonal line—are a lake-colored brown. Each one of the diagonal lines is finished at either end with a round orange or gold-colored knob (like the old-fashioned “frog button”), with a single white bristle in each.

This marvellous detail of finish in even the smallest insect excites our constant wonder and admiration.

The cocoon spun so suddenly by the first of these two caterpillars is exactly like the one cut from the wild raspberry, except that the color is a lighter yellow. The leaves are drawn over it in the same manner, and firmly glued to the cocoon. The mystery which this had seemed before was solved by witnessing him make the cocoon, just as you would better understand the Chinese ball within a ball after seeing one cut. He first bent the leaf in the

position required, drawing it up at the end, and lapping it over at the side. Then he spun the fine, creamy threads of silk, weaving back and forth very dexterously, connecting the opening of the leaves with the side of the box. Contracting his body more than one half within this leafy outline, he worked himself adroitly into positions to form its symmetrical outline. I watched his work until very late in the evening, and the next morning further watching was useless. He had "wrapped the drapery of his couch about him, and lain down to pleasant dreams."

More than six months he slept in his cocoon; and now in April, 1878, he is a handsome Polyphemus moth. Very curiously, he came out just *one day later* than the one last year from the wild raspberry. That was on April 19th, and this came out April 20th. This moth is not quite so bright as the male one, and the antennæ are not so large and plume-like; but otherwise it is equally handsome. The second of the two caterpillars, as it spun up a little later, is not yet out, but the *cocoon* has been peered into, and the chrysalis, in the increasing clearness of its rings, and its active movements when disturbed, gives promise of an early exit. There is no danger of injuring

the moth by carefully opening the cocoon which holds the chrysalis, and then its change can be watched as it turns from a dark brown to a lighter shade, and becomes almost transparent before it opens. Since writing the above, a friend sent me from another State, a box with a note—which was read before opening the box—which said, two handsome caterpillars would be found in the box. On trying to remove the lid, I found something was the matter; when lo, instead of what was promised me, two large, scarcely completed cocoons! My disappointment would have been greater had I not known them at once as belonging to the Polyphemus moth. They were busy travellers, building as they went, and in one short journey completing a house, with a speed and perfection of finish which puts greater architects to shame.

The Polyphemus caterpillar is more easily raised than that of any of the other large moths. The eggs are flat and biscuit-shaped, of a chocolate color, appearing like little frosted cakes. I have had no difficulty in rearing them from the egg. As soon as they leave it they are ready for the oak or maple leaf, and eat quietly and almost continuously, making their changes with no trouble, such as the Cecropia

and other horned or knobbed caterpillars have. This year, 1890, I have had two come out early in March ; the first, with broad antennæ, appearing on March 9th, and the other, with narrow antennæ (the female moth), on March 19th. It has remained almost perfectly quiet, has taken no food, being, so far as I can ascertain, tongueless, and has laid 137 eggs on the sides of the glass box, hardly seeming to feel itself a prisoner. The wings are not in the least marred by flying about in the box although eight days have passed since it left the chrysalis. The beauty of this moth is only excelled by the gentleness of its disposition, which cannot fail to make it a favorite with all who prefer quiet manners to bustle and vain show.

DOUBLE DOORS.

In Saunders' "Insects Injurious to Fruits," p. 175, he says of the Polyphemus moth, "An Ichneumon fly, *Ophion macrurum*, the same as that which preys on the Cecropia moth, is a special and dangerous foe."

I have now (April 12, '90) a large Ichneumon fly which to-day came out of its *round* "front door" from a fine Polyphemus cocoon. This is much larger than the *Ophion macrurum*, and answers to the description and figure

of *Ophion bilineatus* (Say,) figured on p. 175 of Saunders. An Ichneumon, answering to *O. macrurum*, keeps him company under an adjoining glass, and *he* walked out of the chrysalis of an *Asterias* butterfly a few days before, and is figured and described in this volume in the chapter "Two Front Doors," etc. So they are not wholly confined to one variety of moths or butterflies, satisfied with stolen winter quarters and food, wherever they can obtain it. The *Ophion bilineatus* is wholly a russet brown in color, except his very large black eyes (which, appearing to be six in number, two very large, very black, and very prominent, and four smaller ones, form no small part of his head). The two pairs of wings are transparent, the legs long and spined, the body very curiously curved and broadening to the end, and the jointed antennæ nearly two inches in length, and quite as long as the body. He is fond of sweets, and uses his very curious mouth dexterously enough in securing grain after grain of the sugar placed for him. It is sad to look at the large well-formed cocoon, with its usual ornamentation of the maple leaf drawn so nicely about it, and think the poor spinner was working so faithfully for his direst enemy instead of securing a safe

resting-place for himself, where he should sleep into his own rightful robe of beauty. The little "front door" revealed the fact that the Polyphemus had become the prey of the Ichneumon—the round door not being quite as large as a "shot";—and on cutting open the cocoon I learned that the *chrysalis within*, instead of being eaten and broken, was scarcely marred at all; unbroken save the small place of exit, as, in this case, *two doors* were needed for his escape. But the weight! Instead of the solid body of the true chrysalis only a perfect *shell* remains.

VI.

HOW I CAUGHT A BEAR.

I WAS walking quite alone, when a slight noise attracted my attention. I looked about me, when, close at hand, and deliberately advancing toward me, I saw—a bear (Fig. 26).

I was not in the least alarmed, which proves how much there is in a *name*, for I did not then know he was a bear.

Determined to capture him, I armed myself with a small twig and a very small cage in the shape of a tumbler.

Instead of resisting, he coiled up quickly into a ball, was tipped into the cage, and this soon inverted over a piece of white paper on a book.

Thinking a leaf might attract him, I put a bit of cabbage leaf under the glass, and soon he was forgetful of his imprisonment in satisfying what proved to be an almost insatiable appetite.

He spent his time for some days in devouring leaves and taking exercise by rapidly travelling about his small prison.

FIG. 26. YELLOW-BEAR CATERPILLAR.

Eat, march, eat, march, was his programme, until, not satisfied with one den, (Fig. 27) he made himself another, and having sealed himself in, I saw him as he was, no more. I afterward found that inside of the second den he formed another (Fig. 28). His winter quarters were secure.

FIG. 27. COCOON.

FIG. 28. CHRYSALIS.

This was in September. He slept undisturbed until March, and then he began to go about again quite freely, but in a new coat. He ate, too, but very delicately. Not leaves, but a dainty sip of honeyed sweets. In September he was a yellow-bear caterpillar. In March he was an ermine moth (Fig. 29).

A white miller, we should say, but when we part his wings we see his body is yellow striped lengthwise, and alternating with each stripe has a row of black dots. And on his wings there is the merest point of a black dot (one on each fore wing, and two on the hinder ones), so very small that you would not at first notice them. But they belong to him, and are always there. For he is not the only bear we have watched through this change, and four or five quiet, dreamy, pointed, black-dotted moths are now in a box close by me, all alike, except a little different in size.

FIG. 29. VIRGINIA ERMINE MOTH.

These are the Virginia ermine moths.

In the same box are some many-spotted ermine moths, something like leopard moths; but whether tiger, bear, or leopard, the name is not derived from the nature, as all are quite meek, and much more like a lamb.

There is one of these white millers beside me now as I write. The same tiny speck on each fore wing, the same two dots on the

hinder wing. He, too, went into his den in September, and came out in March (1879), so white and furry about the head that if as a caterpillar he should be called a yellow bear, as a moth I should call him a polar bear.

The golden eggs of the Virginia ermine moth turn a sage-green color (almost golden green) just before hatching, and the little caterpillars (about one twelfth of an inch in length) are lemon yellow, with dark sage-green heads.

A good deal has been said about the impossibility of raising moths and butterflies indoors. The chrysalids, we are told, should be left out-of-doors in some damp place, only secured from the worst weather, and shielded from positive storms. It is pleasant to have such proof that this is an error, as I have had the good fortune to secure from the moths themselves, who, in spite of these assertions, have opened their various prison doors for me in the past and present month (February and March, 1890), by scores. Every chrysalis of the Io Saturnia (twenty in all) has given up a perfect moth, and several other kinds have also had their opening; among them the *Chœrocampa*, the cabbage butterfly, and two Virginia ermine moths. Many more chrysalids, large and small, await their coming winged

life, without the shadow of a disappointment, if you judge by clearly *alive* chrysalides. And instead of an out-door, all-weather exposure, they have been in a comfortably warm room devoted wholly to them, with no extra moisture, and making no trouble. The gentle coming of these ermine moths—one day a dark-brown casket, the next, without noise or observation, a snowy-winged silent thing of beauty, the most touching thing about them always being the little tiny speck of a black dot—"one on each fore wing, and two on the hinder ones"—that these minute dots, belonging exclusively to these unobtrusive little white moths, should be given them, year after year, never varying, and so marking them as veritable "Virginia ermines," shows as much a superior care as the noting of the "sparrow's fall," or the "numbering of the hairs of our head." As silently as they come, so silently do they live their little life, sipping the sweets offered them with a delicate amber tongue, laying their eggs, small, round as tiny marbles, of a golden-yellow hue ; scarcely lifting their feathery wings to fly from one offered flower to another, and then, not waiting for their life to be *taken* from them, falling asleep *unjarred*, but not unmourned, in their little box prison.

VII.

CRUMPLE-WING.

CRUMPLE-WING (Fig. 30) came out of his winter's sleep in March. He went in in September. He was a salt-marsh caterpillar

FIG. 30.

FIG. 31. SALT-MARSH CATERPILLAR

(Fig. 31, the *Arctia acrea*). But he seemed very much at home in an inland garden. He was on the croquet ground, plodding his way

among rolling balls and quick footsteps, when he was made a prisoner.

He lived on grass, plantain and other leaves, until he wove his yellowish-brown hairy cocoon under his glass tumbler.

I don't know why he came out of his long rest with a crumpled wing. I think he had plenty of room under his glass, and no one touched him before he was perfectly free and walking about in his queer one-sided manner. When a *Danaïd* butterfly, on coming out of his chrysalis last summer, exhibited a marred and crumpled wing, I knew it was because he had been confined in too small a space for his wings to expand fully; and the form of the pupa itself had been compressed by the position in which it was formed, so as to resemble in shape half an acorn-cup rather than a whole acorn, which it looks a good deal like when perfect. Another *Danaïd* had its wing marred by touching it very gently with a pencil's point, in the eagerness to see it expand more quickly. The slightest touch at that time will injure this delicate fabric, than which nothing in nature seems more susceptible of harm. But there was, no doubt, a hidden reason for Crumple-wing's misfortune, at whatever time it occurred. His right wings are

perfect and quite handsome. The hinder left wing but half unrolled, and much shrivelled. The hinder wings are a rich ochre-yellow; the front pair white, dotted with black and ochre-lined. His back is ochre-yellow, with seven black spots down its centre; six on the yellow, and one on the last ring of the body, which is white. Two rows of black spots ornament the sides, and there is one on the under side of the body also. His antennæ are long and graceful, and the microscope shows them to be variegated in color, and with spiky hairs, instead of being feathered. His head and neck-cape are tinged with ochre. At first he appeared so indifferent to food that it seemed doubtful whether he *had* a tongue; and after being tempted in vain with sugared water, he was left some days to work out the question without it. But when next offered a chance to break his fast, it was amusing to see how eagerly he thrust out his short, amber-colored tongue and drew up the sweets, as a child would sip lemonade with a straw. After his long fast, before eating, he had strength enough to tow another moth and two empty cocoons (which chanced to be caught together near him) all about his box, having entangled the claw of his foot in the

loose hair of the empty chrysalis cover. One or two dead moths were placed purposely near him. He walked slowly about them, looking at them with the appearance of an anxious doctor or surgeon, studying the case for a time, and then walking off, evidently satisfied that hope was gone when no sign of life could be perceived. It never seemed to occur to him to attend to his own case, which was, however, well enough, as it would have required as much skill to unroll his shrivelled wing into symmetry as to put into their dead forms a new life. Just as he stands now, with his head and left wing hidden under a leaf of the blooming hepatica, you would never think of calling him Crumple-wing. His best foot is foremost. He is a fine-looking *Acraea*.

FIG. 32. *ARCTIA ACREA*.

VIII.

UNDER THE CAPE.

THE very day Crumple-wing gave up trying to inspect others, or hold on to his own life any longer, another *Arctia acrea* came out. His brown cocoon was larger than Crumple-wing's. In fact so much larger than any one of the kind I had been watching, that a very fine specimen was looked for from it. As other *Acreas* had appeared, who went in about the same time, he was daily expected, and a hope (which rather grows less as moths increase in number), was indulged that his *exit* might be witnessed. A slight appearance of a disturbance at one end of the cocoon had been noticed, and he was closely watched. Just as the tea bell rang another look was given to his glass box ; when lo ! there was a small oval opening in one end of the cocoon, and the moth was rapidly advancing up the side of the box to the top. But worse than

Crumple-wing! Except that he was symmetrical, his yellow black-dotted body was only partially covered by a very short white cape, and two pairs of very short wings, looking like the old-fashioned double-cloak capes, without the cloak (Fig. 33).

Watching him for a little, with a curious mixture of wonder and pity, we left him; when lo! on returning in half an hour he was all right—as perfect and handsome a specimen of the white-winged *Acraea* as could be found (Fig. 34). His cloak had only been packed under his cape. And this is the way he looked before he shook it out.

FIG. 33.

If another caped moth is seen before he has shaken out his entire garment, something more than a tea bell will be needed to prevent a careful watching of the progress. There was nothing of the limp appearance of a new butterfly, to suggest any further development of wings as necessary. His *cape* was snowy and full and downy, and he walked off with the buoyancy and strength of a fully developed and perfectly dressed creature. The black dots upon his wings are more exactly symmetrical than in any of this kind before

noticed. By actual count almost precisely equal in number, as well as alike in shape and size. The color under the throat is a rich orange, and also of the thighs ; the legs being five-jointed, alternating in black and white. The joints resemble the divisions in the stems of rushes, as is the case with those of most moths when examined with the microscope. The last joint terminates in a sharp, black claw, with which he can cling with a force not to be overcome without danger of breaking. His antennæ are spiked, instead of feathered ; and if Crumple-wing is an *Arctia*, as we have supposed, and he seems to answer the description of that moth exactly, this is one of the same class, without the ochre-lined front and the ochre hinder wings. When at rest his wings are roofed or sloped downward, covering the yellow spotted body entirely.

FIG. 34. *ARCTIA ACREA*.

IX.

THE ARCTIAN AND ICHNEUMON.

THERE were still two chrysalids of the Arctian left, and two days after the one had stolen out from under his double cape (all moths and butterflies have the double-cape appearance), one of these chrysalids was seen slowly ascending the glass prison wall, piloted by the head and fore-legs of an ash-colored moth, creeping slowly along with his heavy brown house on his back !

It was another *Arctia*, or "false ermine moth," as those of this gray color are sometimes called. After a little while the chrysalis fell, and the moth was free ; but, as he had "jarred in the gate" (from not being able from some reason to throw off the chrysalis so soon as he ought), his wings were somewhat cramped, and he looked like a second cousin to Crumple-wing.

After a supper of sweetened water, and upon the lighting of the gas (which always puts fresh life into every fibre of a moth), he

shook out his wings very respectably, and showed his appreciation of light as the first object in life. He was of a soft glossy ash color, and his body had three rows of black dots running lengthwise down the centre and sides.

It is no slander to say that he was double-tongued, which, however much to be deprecated in human beings, is really nothing against one who uses his tongue only to gather sweets.

While some of the larger moths seem to have no tongue, the Arctians are usually supplied with two. They are coiled up side by side, sometimes joined together lengthwise, and sometimes quite separate.

The last remaining chrysalis was just like the one of the ash-colored moth, but when it opened, instead of the expected Arctian, out came a large slender-bodied Ichneumon fly! his head bright yellow and his legs alternating with honey-yellow and black. His wings are a brilliant steel blue. He resembles the Ichneumon that came out of the "round" front door of the Asterias, but is larger, and has a sword-shaped borer nearly half an inch in length, giving him rather a formidable appearance, as he comes buzzing in his "April fool!" with a bold whirr, instead of stealing in softly with the meekness of the feather-winged Arctian.

X.

THE WHITE ERMINE MOTH.

I FOUND him one November day,
A stiffened circlet at my feet,
And made him prisoner in my room,—
His brown coat glistening with the sleet.

Awhile he lay as still and stiff,
As though his little life were o'er,
Then yielding to the new-found warmth,
Shook off the icy pearls he wore,

Surveyed awhile his crystal walls,
Shut in from liberty and—cold ;
Then built an inner prison wall,
Closely his body to enfold.

He seemed to sleep an endless sleep,
Silent and still so long he lay,
When lo ! in robes of snowy white
He sprang to life one winter's day !

XI.

A HUNDRED TO ONE.

WE had been looking in vain for caterpillars on grape-vine, walnut, and sycamore, when we stopped before a large woodbine, which threw its clusters over the side of my friend's piazza, in Pittsfield, Mass. We sent our eyes upon a voyage of discovery, and peering among the thick matted mass of green—

“Oh, here is a fine fellow,” exclaimed Teddy, the eager little boy being the first to discover a pale green caterpillar, so nearly the color of the vine that the similarity was his greatest protection.

“Here is another, and another! They seem to be out in force to-day; but these are so high up—how shall I reach them?”

“I'll get a step ladder,” said Teddy; and disappearing behind the corner of the piazza, he soon came back tugging the heavy steps,

and placed them under the woodbine. Now for some tumbler. They were soon brought, and the caterpillars imprisoned before they knew it, eating on the leaf which had been clipped from the vine without even disturbing their dinner. It was well we secured as many as we did, or even one moth might not have repaid us; for the caterpillar of the woodbine, in common with many others, has a secret

FIG. 35. *CHÆROCAMPA PAMPINATRIX.*

little enemy, from which he is not apt to escape. These nice-looking ones with such good appetites, however, did not seem to have any lurking danger. But one can not always tell. Damocles was not the only one over whose head hung a sword while he was enjoying his repast. Teddy selected two of the best—not to keep himself—but for the friend who was helping him hunt them. The cater-

pillars were soon separated ; Teddy's remaining where they were found, and the two others going a long journey. Pretty soon some strange things appeared on Teddy's caterpillar. He ate on, but looked rather dispirited, as if he had caught a glimpse of the hair by which the fatal sword was suspended. Soon he was walking about with something all over his back, which made him look as if he had taken a bath, and then rolled about in a box of rice ! (Fig. 36.) The microscope showed these rice grains to be perfect cocoons, white and silky, and each looking as if a little cover were fitted to one end. Something moves inside of these. Some of the little intruders are still working on the inside of their rice-houses, polishing the ceiling and giving the finishing touch to the walls.

FIG. 36. CATERPILLAR WITH
ICHNEUMON CHRYSALIDS.

By and by they are completed, and then the woodbine caterpillar begins to grow weaker. After a week or two, these little covers begin to fly open, and as they lie back on their hinges, out of each one creeps a small fly, and begins to go up the glass.

He is a prisoner, and we can study him. He is one of our old friends, a species of

Ichneumon, with ugly mouth, jointed antennæ, hooked feet, amber legs, and thin, narrow wings. He is very small,—but there are so many! The poor caterpillar cannot stand it. A hundred to one is too much, and by the time that over one hundred of these swords have pierced his body, he was, as Teddy's grandmother said, "very dead." Here is his likeness, which an artist took for Teddy's friend. You can only see his head, one or two wings, and one foot (Fig. 37).

FIG. 37.

FIG. 38.

But the two caterpillars which took the journey seemed to escape this trouble. They both soon went into chrysalids. One drew a

leaf about him, and fastened it with a few glossy hair lines to the bottom of the glass; the other made a hint of a cocoon, with a thin network of gauze-spun threads, and twenty days after came out a pretty moth—the fore wings olive gray, banded and shaded with olive green, and the hind wings a reddish-brick or rust color. . Both pairs of wings were uniquely scalloped. The chrysalids were, first a sort of mulberry color, irregularly spotted here and there, and the one which opened, growing brown (and a very dark brown between some of the centre rings), just before coming out. The second chrysalis (Fig. 39), formed some days later, is brown and dark-ringed; but as it is a fortnight since the moth made his appearance, he is taking it very leisurely, if he appear at all. This caterpillar and moth answer to the description given by Harris of the *Chærocampa*, or hog caterpillar (which seems as great a misnomer as that of the *Polyphemus*), from a fancied resemblance of the head to that animal—the head of the caterpillar being small, and the fourth and fifth rings very large, and tapering to the small head.

The moth has been named *Pampinatrix*,

FIG. 39. CHÆROCAMPA
CHRYsalis.

from its living on the shoots of the vine. The caterpillar lives upon the grape, as well as the woodbine. In Harris' description, it is said that the moth leaves the chrysalis "in the month of July, of the following year." But this (as most other moths) has an opportunity of trying the world twice in the course of a year. Some very large caterpillars—four inches in length, and as large as one's finger or thumb—closely resembling the *Chærocampa* in shape, have since been found on a woodbine in Pennsylvania. They were, however, so completely covered with the "rice-houses" (more than a hundred to one) that they were not kept. Only, the parasites were brushed from one into a box, and now the "syrup cups" are opening, and a perfect colony of *Ichneumons* are running up and down the glass, wondering how they came to be born in prison.

March 23, 1890.—A beautiful *Chærocampa pampinatrix* has come out of its brown, sharp-pointed chrysalis to-day, and makes a pretty picture, hovering over some blue periwinkles in his glass box. But although their little cup-throats have been filled with sweetened water, he does not deign to uncoil his umber

tongue to take a sip. Just the front of the three-grooved wheel is to be seen. No doubt if he were flying "in fresh fields and pastures gay" he would soon find a use for it, but he is far too early for such a feast and would soon die if given his liberty. So he must use the periwinkle cup or starve.

Close beside him, on the same box of earth, is his exact mate, who travelled with him over the mountains of Western Pennsylvania last August, and who, doubtless, will not be far behind him in the spring opening. They were taken from an evergreen honeysuckle and sent me as caterpillars, making their chrysalids soon after their long journey, without a hint of a cocoon, although the *Chœrocampa* usually makes a very thin veil-like covering for the chrysalis.

As described, at the time they were received (August 15, 1889), they answered the description of those given in "A Hundred to One," and the moth is the same as there described. On reading a description of this caterpillar in Harris, and in Professor Lintner's "Fifth Report on Injurious Insects," I was at first surprised at the difference, until I remembered how many of the caterpillars that I have raised

from the egg change in their appearance almost wholly. This one I had only seen when nearly ready for its change. At one time it is gayly marked down the back with spots of yellow, edged, in part, with rose-red. And, in his description, Professor Lintner says that shortly before changing to the chrysalis "the color changes to a dull rose throughout." If these assumed that color it was either a *very* "dull" rose, or I was not fortunate in the time of watching them. In some lights, with a stretch of imagination, the faintest hint of a pink flush may have relieved the yellowish-brown. However this may be, the moth is the same, so there is no doubt of his being a true *Chærocampa pampinatrix*. He is a handsome moth in shape and shading, the upper wings crossed in bands of gray and olive-green and edged with a red rust color; the under wings being like this narrow border, a rust-red. He is very still most of the time, but when he does use his wings they quiver and thrill and shake so fast that it is almost impossible to see them. The *Chærocampas* which I have had have been those only from the honeysuckle or kindred vines, but he is sadly complained of as a grape-robber, eating the leaves to the destruction of many a vine,

and cutting off the young stems of the clusters, which he does *not* want for his own use, until the ground is strewn under the vines with tiny green grapes.

XII.

THE UNFINISHED LIFE OF QUAKER GRAY.

I HAD a little Quaker, dressed
In starry robe of gray,
With silken tufts of black and white
Completing his array.

His home was on a Quaker leaf,
A poplar, silver-lined ;
On this he lived, from this he ate,
Beneath my glass confined.

If frightened, he would drop the fringe
Of tufted black and white,
Putting his jetty, varnished head
Completely out of sight.

One day, when he grew very tired—
Tired of his poplar leaf,
Tired of his small glass prison and
His little life, so brief,

He climbed his crystal wall, and wove,
In silence all the day,
A Quaker hammock for himself,
Of tissue silvery gray ;

Wove it about his bead-like head,
About his feet, so queer—
Ten feet behind, like amber spools,
So yellow and so clear,

And six in front, like tiny horns—
So, fastened in his net,
Day after day, as still as death,
Hung the poor Quaker pet.

One morning, slowly out he crept,
And a fresh suit he wore,
But, to my disappointment, just
Like what he had before.

Perhaps a little longer waved
His tufts of black and white,
Perhaps a little glossier grew
His silvery coat, so bright.

Weeks passed ; a closer net he wove,
Again of sober gray,
And, self-immured, profoundly slept
His second life away.

More than a year for coming wings
I watched that tight-locked cell.
Still closed remains his prison door,
And now I know full well
That this short tale of Quaker Gray
Is all that I can tell !

FIG. 40. COCOON OF CECROPIA MOTH, CONTAINING CHRYSALIS.

XIII.

AN EARLY CECROPIAN.

TWO rough brown oval cocoons, spun (with one flat surface fastened lengthwise to a branch) by the large green caterpillar of the *Attacus cecropia* moth, were brought in, and lying side by side, looked as nearly alike as possible. From one of them, on March 1st, as if to show his appreciation of spring, the fine Cecropian stole out which is now in the glass before me. The other cocoon, from eagerness to see what promise it gave of a mate, was carefully cut at one end ; when lo, an empty chrysalis within ! Even with a microscope no place of exit was to be discerned. But his cast-off

FIG. 41. CHRYSALIS OF CECROPIA MOTH.

dress was in the tomb, and it was evident he had, with more skill and silence than the vanishing Arab, gone off *without* his "tent," to enjoy the freedom he could not have had, had he been born in prison. I could easily believe the remark of Harris, as I searched in vain for the "front door," that the threads of the cocoon of this moth "converge again by their own elasticity, so as almost entirely to close the opening after the insect has escaped." In fact, I could omit the "almost." The change is indeed marvellous from the large light-green and coral-dotted caterpillar (making one think of a cactus stem that had concluded to walk off), to the gray, white, and cinnamon-brown moth (Fig. 42). The six legs and most of the body are cinnamon-red. The broad brown antennæ, with central amber stem, come out from the front of the rather small cinnamon-colored head. Just back of this a neat white collar, and then the tufty brown extends back half an inch, and from it proceed the wings. Then comes a narrow band of lead color, and the rest of the body is ringed with black, white, and cinnamon-red, alternating. Along each side are seven round cinnamon-red spots, bordered with white. The finish of the hinder wings, in heavy lines of alternate gray and

black, reminds one of a pheasant's wings; but above this border is a line of the red, and above that a narrow line of white. In the rich furry grayish-brown of the hind wings are two large crescents of red and white. The front wings have no white in the stripe above the beautiful scalloped gray and reddish-white. They have an eye spot near the edge, of very dark brown or black, edged with white. It is a very rich moth, though not as soft in the harmony of its colors as the *Polyphemus*. Like that it is very gentle in its manner, keeping almost entirely quiet during the day, and flying but little in the evening. Its eyes are black. If it has any tongue it is not to be seen, at least while the moth is living, even with a microscope; nor can the moth be tempted to use it. Its wonderful tenacity of life, when this fact is considered, is very remarkable. It will live about three weeks apparently without food, and pays slight attention to any thing ordinarily used in putting moths to sleep! The moth stands most of the day with its wings almost together, but will slowly open them to their full extent if blown upon slightly. The caterpillar may be found upon the apple, cherry, or plum-tree, and changes, from being at first a deep yellow,

FIG. 42. THE ATTACUS CECROPIA MOTH.

to its last coat of handsome light green, before going into its chrysalis (Fig. 41). It is said by Harris to come out in June, but, whether on account of the very mild winter and the usual difference of climate between Massachusetts and Pennsylvania, or as a surprise to insect lovers, this *Cecropia* is three months in advance of that season. So early an exit will make less difference to a moth without a tongue. There are three fine cocoons of the *Attacus cecropia* before me, in a box (opened at one side so that the chrysalids can be watched), as I write (March 29, 1879), and by the transparent lines between the rings one of them shows it will soon release its impatient prisoner. The *Cecropia* worm spins its cocoon invariably alongside a twig or branch, as shown in the cut, when in the orchard or wood. But one of these three (the caterpillar of which was confined in a glass jar) made his cocoon of the usual shape and texture, except that the material is a richer, glossier brown, but it is not attached to a stem. It was fastened to the side of the glass by a heavy web of dark silk, very much darker than the cocoon itself, which is a handsome russet-brown. The inner lining is very glossy, and the whole fully three inches long.

The Cecropia moth is more difficult to raise "in prison" than either of the other three large moths (the Luna, Polyphemus, or Prometheus) of this genus, Attacus.

On July 8, 1889, I received a box with a large number of the eggs from a friend in New Jersey, all of which came out (several having hatched by the way). One peculiarity I noticed at the start with them all—they do not eat the egg upon leaving it, but just enough to allow their escape. They began at once to eat the lilac,—and the pear,—as well as the currant-leaves which were given them. I have been more interested in this fact (of which I made a note at the time), from a discussion of this point between two of our best entomologists, since my notice of the Cecropias, one asserting that the eggs of butterflies—and I suppose moths as well—were *always* immediately eaten, and the other as strongly saying it was *not* always the case. I have since watched many different caterpillars in this respect. The Danais eggs were eaten usually as soon as vacated,—every vestige gone in a little time, except in a *few* cases, where the Asclepias leaf was ready at the little open door, and probably had a fresher attraction for the escaped prisoner than his

prison walls. But in other cases, notably in nearly a score of eggs of the rosy *Dryocampa*, the empty shells remained, and are preserved in an insect-egg collection, whole enough (and brilliantly glossy) to show the shape and material perfectly. This is also the case with a group of most exquisite pearly eggs, found opened and deserted, of the still unknown occupants. So that unless an entomologist knows *every insect* of the millions, in their first and latest habits, it would probably be safer not to make assertions *for the whole*, which a *part* may rise up and prove mistaken.

The *Cecropias*, in their *first* stage, are chiefly black, and spined on all the rings, each spine (plainly to be seen with a microscope) having three or four hairs, or finer spines. A *few* were yellow in this stage (as Harris gives them), but most of them were quite black. In the *second* stage, the black coat is exchanged for one of russet yellow, with black spines, which are each spined, in wheel-forms, with one russet-yellow spot, or knob, on each cluster of spines. In the *third* stage they are *bright* yellow, the wheeled spines jet black, like *spokes* of spun black sealing-wax, from *hubs* of clear garnet beads, one bead, or knob, being the centre for four, five, or six spokes.

In this stage also, the *second* and *third* rings are very handsome. On the top of the back, on each of these two rings, are two *crimson* "hubs," spoked with black. The next to the last pair of knobs, or hubs, are a pale indigo blue, and this color is hinted at in several of the knobs toward the end, all being spined with the jet black spines. In the *fourth* stage the color is a very pretty light-green. There are large coral-red warts on the second ring, and smaller ones of the same color on the third, while on all the others to the eleventh there are yellow, egg-shaped prominences, beside which there are two rows of light-blue beads, or warts, each side all the length, and one row of the same color on the side (below these) of the first five rings, giving the whole caterpillar a "coat of many colors," sufficient to excite the envy of all his acquaintances. But he pays dear for that part of his ornamentation which consists of *raised work*, and which not unfrequently costs him his life when attempting a change of garment.

[NOTE.—The easiest way to transfer the imago from the box where it has completed its change to the cyanide jar (and which does not necessitate touching or alarming the moth), is by holding a narrow-folded strip

of paper before it, upon which it will invariably step, and both paper and moth can be dropped quietly into the jar. So many moths are rubbed and defaced by rudely taking them between the fingers and thrusting them into the jar that it seems to me this simple and successful way is worth mentioning.]

XIV.

THE ROSY DRYOCAMPA.

I HAVE been April-fooled several times within the last hour. Not by a person ; but by a moth—my beautiful rosy *Dryocampa*. It was no April fool, but a pleasant surprise, its coming out this April morning after its long sound sleep, never once moving, in the black ring-notched chrysalis, since it went into it on the twenty-sixth of last August. A beautiful little creature it is, especially the under wings, which look, more than any thing else, like a stray rose-tinted sea-shell, such as one sometimes finds, nearly transparent, and almost as flat as a rose petal.

FIG. 43. *DRYOCAMPA RUBICUNDA*.

I was trying to sketch it, and it would stay so perfectly still that I would think, "Now, I

shall have a good chance!" and lo! when one wing, or the crested head, was half drawn, away it would fly. Recaptured, I would begin again, and with the same success as before; so that when I had about six half-finished sketches, in as many different positions, I remembered it was the first of April, and quietly put it under glass, until the picture was secured.

There are but two colors, rose and yellow. The upper wings deeply bordered with rose behind, and broad epaulettes of the same color. The under body and feet are rose color also, and there is the faintest hint of rose on the under wings, which are studiously kept out of sight. All the rest is a bright yellow. The head is tufted, and the eyes are set so far under in front as not to show, unless you peep under the tuft, where you see them, black and round, close to his little front feet. There is a triangle of yellow, bordered with red, between them, and a little triangular tuft of the same color at the base of each of the delicate antennæ. Much of the time when the moth is at rest these antennæ are completely hidden, by lying back close along the edge of the front wings (like those of the *Quinque maculatum*), so that you would be apt at first to think he had

none. They have about thirty joints, as near as one can count them when in such constant vibration as they are pretty sure to be when in sight. He will keep perfectly still two hours at a time (if you are not attempting to take his picture), then fly about wildly for two or three minutes, and then for hours remain immovable, as if dead. This one prefers to stand showing but three feet—two on one side, and one on the other,—and no coaxing draws out the shy foot. The under wings are kept out of sight, except a little margin in front, near the head, which shows a small crescent of faint rose color below the upper wings. The antennæ of the female moth are simple, like a little strand of beads, while those of the male are spined, being larger, as are those of all male moths. The only other moth of this kind which I have seen went into the chrysalis state in the summer (July 5, 1877), and came out the last of the same month (July 27th), perfecting in that time the work which—however soon completed in the fall caterpillar—remains out of sight nearly half a year. Harris, in the description of the rosy *Dryocampa*, says, "The caterpillar is unknown to me," and I have not seen it described elsewhere. The two which I had (one of which I watched

through the change into the chrysalis) were taken from beneath the maple tree, and were nearly ready for their change. They do not spin any cocoon, nor attach themselves to the glass (like the caterpillar of the *Danaïds* and also of the *Asterias*, and others), but work off the caterpillar skin—the chrysalis first appearing of rather a bright green or yellowish color, and soon becoming quite black.

The *summer* chrysalis would move, when touched (advancing on the paper with a peculiar gliding motion, by means of the toothed edges of the rings); but the winter one was never seen to move a hair's breadth. The caterpillar has twelve rings, is a pale pea-green, and striped lengthwise (which gives it a somewhat checkered appearance) in narrow stripes of a little deeper shade of green. The head is a russet-brown color, and there are two soft black horns on the second ring about one third of an inch in length. The under side of the two rings before the last are a purplish-brown, edged all along with short, black spines. There are a few short, black spines on the last two rings, and the V-shaped tail is edged also with a border of them, as also is a line along each side of the body. There are minute black warts symmetrically arranged about each ring,

about five on each. It is curious to compare a butterfly or caterpillar either with another or with some written description, and notice the exactness of repetition in spot, spine, and marking of every sort. In writing as minute a description of a certain caterpillar as could

FIG. 44. CATERPILLAR OF DRYOCAMPA RUBICUNDA.

FIG. 45. CHRYSALIS OF DRYOCAMPA RUBICUNDA.

be given from counting both spots and spines, I was pleased to find afterward a printed description answering count for count. There is not always the same similarity in their *cocoons*, as they will accommodate themselves to cir-

cumstances rather than give up the idea of building their home. The Polyphemus will always draw leaves together in a graceful manner about his cocoon ; but one, from whom I took his supply of leaves, when about to spin, made his cocoon without it. It is true he was the only one of several which I had who died in his cocoon ; whether from mortification that he was obliged to deviate from his usual plan, I never learned. But the *chrysalids* (except from some malformation) seem to be as exactly similar as the moths and caterpillars.

The eggs of the rosy Dryocampa moth are very handsome. To my surprise I found (August 28, 1889) a beautiful cluster of these eggs (seventeen in all) on a leaf of maple ; some of the tiny caterpillars just emerging from their bead-like cells. With the microscope I could at once identify them as those of the rosy Dryocampa, which I had not before known in its earliest stage. The eggs were very shiny and glass-like in finish, light pea-green, and globular, with a plain surface. The little caterpillars, with dark, almost black, heads, and bodies pea-green, striped lengthwise, and the two little horns or feelers on the second ring from the head, showed them at once to be rosy Dryocampas. In coming out they

had only eaten the *roof* of their glossy green houses, and the lower half of the little circles still glisten on the maple leaf where they were first found. The caterpillars grew well in confinement, and each one of them now lies, a fine chrysalis, waiting for some fair day to come out from its dark, notched case, with rose and yellow wings, triumphant in the change.

FIG. 46. DRYOCAMPA RUBICUNDA MOTH.

XV.

THE SATURNIA IO.

THE handsome Indian yellow moth, *Saturnia Io*, was one I learned backward. Finding a beautiful moth of this kind on a fence one evening at twilight, I secured it with delight,

FIG. 47. SATURNIA IO (FEMALE MOTH).

but with no knowledge of its name or from what sort of chrysalis or caterpillar it had come. After keeping it some days, I found

it one afternoon apparently dead. Touching it, or moving it along even, with a pencil, betrayed no sign of life, and it was carefully placed in a box containing several other specimens. While reading in the same room that evening, I was startled by an unusual sound, which, as I was alone, was a little annoying at first, but soon I perceived the noise came from the direction of a box of moths! And sure enough, my *Saturnia Io*, far from being dead, had taken occasion to call on each particular moth in the collection in the most unceremonious manner, ascertaining to its entire satisfaction, if not to mine, that none of the others had been put away (not to say buried) alive. Some delicate wings were detached from poor victims unable to return this unmercifully swift whisking about; and before the *Io* could be safely transferred to solitary confinement, he had brought confusion out of order in the most undesirable manner possible. So began my acquaintance with *Io*. In the latter part of the following August, a caterpillar was given me by a friend, of a kind I had not seen before, and soon I found two others like him. They were between two and three inches long, and of a light pea-green color. The twelve rings were each starred with a cluster of green spines,

tipped with a dark purple, looking almost black. These were sharp and thorn-like. A line of purple brown ran along the lower part of each side, bordered on the lower edge with yellow. The hinder prop-feet were a dark brown; the eight middle feet purplish, with a brown finish

FIG. 48. SATURNIA IO CATERPILLAR, WITH THE THREE GRADES OF SPINES.

at the bottom. The three pairs of true feet were purple. The head was green like the body, while the mouth was purple like the feet. The first ring was so completely covered with spines as to hide his head entirely when bent forward, as they usually were. There were six

sets of these stars on each ring, except the last two (and five on each of those), and on the first four rings, which have on each side an extra cluster very low down.

These spines are very stiff, and remind one of porcupine quills. The purple-brown line along the side, which begins at the fourth ring, bends down to the hinder prop-feet, leaving five clusters on the last ring. On each side of every ring is an oblong vertical breathing hole (spiracle), as in nearly all larvæ ; for though these differ in number and some other respects in different caterpillars, yet their arrangement is uniformly symmetrical, and usually each segment is furnished with a pair. Examined with a microscope, this spiracle has first a vertical white centre line, around which is an oval of brown, and this again bordered by an outside oval of jet black. He looked like a moving strip of star moss. He refused clover, dogwood, and elm, all of which they are said to like, probably because when taken he was about ready to become a chrysalid. There are in each star about thirty spines. Three shorter ones usually in the centre, a second circle about these three, and again a third, which are still longer. Some of the spines, especially in front, are not tipped with

purple, but end in delicate long hairs. While really pretty, they are a formidable-looking caterpillar, and the sting of the spine is said to be as severe as that of a nettle. So curious a caterpillar was not difficult to be found described, and I soon learned, if these went safely through their changes, I should have the *Saturnia Io* moths. In a very short time the three had spun their cocoons and retired for a winter's sleep. Two of them seemed to strike up a close friendship at once. While the third went off to a corner of the box and spun his cocoon independently, the other two worked

FIG. 49. CHRYSALIS AND COCOON OF SATURNIA IO.

closely side by side, forming a twin cocoon, joined together entirely on one side, and looking not unlike a double covered cradle. This being a new departure (as in the case of the *Polyphemus* cocoon, without the leaves on the outside), only one of the pair survived the experiment!

On the last day of winter (February 28, 1878), one of the covered cradles opened, and a beautiful female moth came out (Fig. 50), just such an one as had made the bustling expedition

among the box of specimens in the fall. On the third of March the single cocoon opened, and a male *Saturnia Io* appeared (Fig. 51). It is of a deep Indian yellow, with the four wings obliquely marked with purplish red, and a number of spots on each, close together, near the middle of the wing, which, have been thought to resemble the letters A H, and which, with a little help of the imagination, do look more like those

FIG. 50. FEMALE IO.

letters than any thing else. His mate is much darker, with less of the yellow and more of the brown and purple. Instead of the letters A H, there is a three-scalloped spot of rich, deep brown, edged with gray. The head is a rich snuff-brown, very velvety, and the handsome, velvety feet are of the same rich color. The other half of the double cocoon remained unopened.

After writing the above, it was my curious good-fortune to find seven of these large caterpillars on one blade of Indian corn. There was not another to be found in the small field, and how these had chanced to congregate in such camp-meeting array was a mystery. They are "processionary" caterpillars, and although I had read this, I should not have realized it but for the curious sight which having so many at once afforded me. After they had been put

FIG. 51. MALE IO.

under a large glass, it was a new and amusing sight to watch them march around—one lengthened, mossy line of green, all touching one another and walking as fast as if quite alone. They preferred the green leaves of the corn to any others which they are said to like and will eat. One after another they made their seven cocoons, and lay through the winter just passed, side by side, a little hamlet of sleepers—houses

so still and apparently unoccupied as to have suggested a "Deserted Village," but whose occupants I knew were only waiting to surprise me on some coming spring morning with a regular Chestnut Street parade.

And the spring opening has come. Three of the sleepers have left their black, moveless, chrysalid homes. One has lived his little life, and two rich brown and purple ones are in a box near me (March 31, 1879). One of them has just made a pretty picture by flying upon a fresh light-green blade of Indian corn (planted in my room expressly for their pleasure), almost, but not quite, too frail, in its own forced and tender growth, to support his swinging and fluttering little body. The corn was not for them to eat, as these moths may be classed among the tongueless ones, nor could they get any good from the green blades, had they ever so long a tongue. But if it were June, and they were in the cornfield, there they would deposit their eggs for the future star-moss caterpillars—more than two dozen of which, rather large, and of a clear, golden yellow, are now in a box, with a leaf of the corn for any possible coming need.

The pupa is black throughout, so that there is no change in it to indicate the coming of the

moth, as is the case in so many of the brown or other lighter-colored pupæ. The rings, however, become a little wider apart, and the spaces a little clearer, perhaps, between them. The end of the pupa, opposite the head, when looked at with a microscope, is drawn in a little curiously, reminding one of the peculiarly pretty bud of the laurel blossom.

Another cocoon has since opened (April 10, 1879), and a lemon-yellow and variegated male *Io* has shaken out his beautiful wings, handsomer in his light spring suit than any of the others.

XVI.

SILVER GRAY.

STANDING on the heart of a blush rose, with his richly shaded, silvery wings fluttering over its soft petals, my *Quinquemaculata* moth makes a fine picture. His wings are spread just enough to show five orange spots encircled with black, which ornament each side of his body and give him his name. But the back of his head, between the shoulders, is his chief beauty. It is a rich, soft gray, curiously and regularly watered with black and white wavy lines. Of his six legs the last two pair are branched with three delicate spines. The eyes are very large and velvety black. The antennæ are not feathered, as are those of the *Polyphemus* moth, but many-jointed, tubular, and finely pointed at the tip.

These antennæ are about an inch in length, and usually lie back close to the side of the

body, seeming to form a corded edge to the upper wings, the points lying just under the wing. You would at first say he had no antennæ; but watch him a little, and they will soon be very apparent. The tongue is four or five inches in length, but when coiled, looks* like a small wheel set between two feathery side pieces.

When freed from his chrysalis, his first care seemed to be for this long slender tongue, which had been so specially cared for, during the chrysalis state, in its curious pitcher-handle sheath. He unrolled and shook it again and again, curling and smoothing it as a child would a dandelion stem, and then reaching up, touched the top of the glass box (quite a high one) several times. Then he coiled it up quickly, and that was the last seen of his long tongue, except the hint of it in wheel form. Although tempted by fragrant flowers and sugared moss, he would not be induced to uncoil it again. A "greater green orchis," with its immensely long nectary of sweets, would no doubt have given him an opportunity to satisfy his hunger in a becoming manner; but no such flower was at hand, and scorning to use so remarkable an organ upon any ordinary repast, he quietly became a martyr to his

FIG. 52. *MACROSILA QUINQUEMACULATA* MOTH.

sense of propriety, and died from hunger in the midst of plenty. And what is this dainty creature ; or, rather, what was he ? You will exclaim when I tell you he was the revolting-looking, large, green tomato worm.

Snappish and really dangerous in that form—requiring to be taken with great care—the change in his disposition seems as great as that in his external appearance. Although he does not equal the Polyphemus in gentle-

FIG. 53. LARVA OF THE QUINQUEMACULATA MOTH.

ness (and I have seen no moth that does), still he is timid and quiet ; although I fancy when touched there is a trace of the original disposition in the short, quick flutter he gives in response. It has not been an easy matter to secure this moth. It is a sphinx, and like all this class the caterpillar buries itself in the earth to go into the chrysalis form. Several large specimens of the tomato worm were caged in boxes, upon earth, and fed with to-

mato leaves. In due time they all disappeared in the earth. The same curiosity which leads children to take up seeds once or twice to see if they have sprouted, led to several attempts to see if these chrysalids were formed. Though Nature cannot be delayed, neither will she be hurried.

At length, all the earth being shaken from them, two large well-formed chrysalids appeared. These were allowed to lie upon

FIG. 54. CHRYSALIS OF THE QUINQUEMACULATA.

the earth all winter. They showed signs of life until March, when they shrivelled a little, and would no longer move when touched. They are now "hardened cases," with no hope of change.

This was too great a disappointment to bear without some attempt at remedy, and the thought was suggested of digging where last year's tomatoes had grown, to see if any unwatched ones had survived. The gardener soon brought two fine chrysalids to light.

U. S. N.

They were laid on boxes of earth in the empty glass case which the others had occupied, and Silver Gray broke the bands of one of these yesterday. The large moth made its exit at the usual place between the shoulders, leaving a mere parted line in the almost unbroken chrysalis. Even the long tongue-sheath was not broken or loosened from the breast. These two chrysalids were alike. The first two differed only in the tongue-case, one having the pitcher-handled case, as in the engraving, while the other had two short, straight cases, side by side.

What may we not believe possible in transformation, when we see the forbidding to-mato worm, after a dark underground existence, come out into the silvery beauty of the *Quinquemaculata*?

Shall *we* fear "the dark prison of a tomb," since the same power that opens the chrysalis rolls the stone from the long-sealed sepulchre?

FIG. 55. CERATOMIA QUADRICORNIS (HARRIS).

XVII.

CERATOMIA QUADRICORNIS (HARRIS).

I HAVE dipped the bells of the lily of the valley in sweetened water and put them in the box where my fine moth, *Ceratomia quadricornis*, may have a rich treat. But, as usual with these long-tongued moths, he scorns the feast, although his mouth waters for it, as one can see by the way the little brown wheel moves between the "tongue-cheeks."

For five minutes he has had his head buried in a lily bell, but not a muscle moves, as I watch him with my glass. Had he plunged it

in himself, he no doubt would be sipping sweets, but as it was put over him, in a way he did not understand (nor resist), he simply scorns a forced meal.

He is a very richly shaded moth, with, however, no bright colors. He is a little larger than the *Philampelus*, or "vine lover." He is a rich brown, light, with very dark wavy shadings, like watered silk, with a very little white. The body has five lines running lengthwise, of the darkest brown shade.

The caterpillar lives upon the elm. This one came to me in a box from a friend in New Jersey, August 10, 1881. The moth derives its name from the large, green, rough caterpillar, which has four horns on its shoulders (Fig. 56). These horns are evenly and curiously notched.

FIG. 56. CATERPILLAR OF *CERATOMIA QUADRICORNIS*.

There are seven diagonal lines on the sides, and down the centre line of the back there is a row of notches like the teeth of a saw.

There is a horn or spine on the end of the body—a continuation of the notched line of the back. I had found one of these on an elm in Pittsfield, Mass., two years before, which died in the transformation to the chrysalis. It is very difficult for these horned caterpillars to make the change into a chrysalis. And as I only laid the one first secured on the top of a box of earth he had a very poor chance to effect it. He was, at first, a fine noble-looking fellow, but in his efforts to change into the chrysalis he became the most forlorn-looking of creatures. His little amber-colored feet were brought together (in pairs), almost touching, like folded hands. You could only see that he breathed by their gentle rising and falling; and even this would cease for such long intervals that one would think him dead. His skin shrivelled until it looked like the brown netted meshes of a nutmeg melon rind, and after a few more faint efforts he lay still, not to move again.

When the fine specimen given me, August 10th, was first received, he was evidently ready for his change. He was placed upon a box of earth, and in less than an hour (after describing a very correct horseshoe in one voyage of discovery on top of the earth) he went quickly

out of sight, and remained for months undisturbed. In March he was uncovered, a fine large brown tongue-cased chrysalis, and watched as his wings grew farther apart and a little clearer, until, fortunately when my eye happened to be upon him, I saw him break his casket, and step briskly out and walk up the side of the glass box (upon the ribbon edge) in about three seconds of time. I say fortunately, because those who watch chrysalids know how very certain they are to spring upon you in full-dress when your back is turned for a moment. Out of eleven *Saturnia Io's* which opened this spring, equally watched, *not one* was seen during the exit. It was perhaps an hour before his wings were entirely shaken out, but such perfect unfolding, without wrinkle or seam, after such long and *tight packing*, is not seen from any traveller's trunk!

FIG. 57. PHILAMPELUS ACHEMON.

XVIII.

PHILAMPELUS ACHEMON.*

“ONLY honey-dew, and sweet manna !
 No more grape leaves for him !”
 Strange words to say bending over a large ungainly caterpillar, one would think, and yet I knew why he was hurriedly making his way out of sight in the box of earth on which I had not an hour before placed him, and why, as well, he had turned from the fresh leaf of grape I had just brought for his supper. No more grape leaves—done with coarse food and low grovelling life ; no more crawling and creeping

* Vine-loving Achemon.

and half-blind existence. A long, quiet rest, out of all sound and sight, and then a fresh, bright awakening to soar and sip from the daintiest flower chalices, in the exquisite garb of the gentle *Philampelus achemon*. This I knew was before him, although I had failed the year before in an attempt to see him through these changes, farther than the chrysalis, which I had probably prevented reaching its perfect state by exposing it to the sunlight before I had learned that it should have darkness rather than light until the time of its winged awakening.

It was on the first day of October ('81) that I spied him, at the close of a game of croquet we had been enjoying, slowly making his way down a fence-post, beneath the grape-vine. An odd enough, and not very prepossessing-looking fellow (Fig. 58), in his russet-brown

FIG. 58. CATERPILLAR OF PHILAMPELUS ACHEMON.

dress with diagonal cream-colored side-stripes, six on a side (made up of a sort of chain of twisted oval spots), and a curious staring eye-

spot on the top of the last segment of his body. More odd still, when disturbed, he drew his head and the next three rings of his body into the fourth ring, making a monk of himself without ceremony (Fig. 59).

FIG. 59. CATERPILLAR WITH HEAD WITHDRAWN.

Placed upon a box of earth, (covered with glass), in less then half an hour he was out of sight.

Tipping the box carefully, a few days after his disappearance, letting the earth slide from him to disclose his successful change into the chrysalis (a large chestnut-brown case), I covered and put him away (Figs. 60 and 61).

There he slept until May 14, 1882, when, looking at the box again as I had for some days been doing, his hour of triumph had

FIG. 60. UPPER SIDE OF CHRYSALIS.

come! I saw, standing above the open chrysalis the beautiful *Philampelus achemon*, his

wings trembling and expanding into his now perfect dress. His eyes are very large, the antennæ long, slender, and pectinated, and you have no need, as in the case of the *Polyphemus*, to search for his tongue, as its large coil shows like a brown wheel between the deep rich velvety side-pieces, or tongue-cheeks, which enclose it. As he stands now, on a bunch of cherry blossoms in his large glass house, with his curiously scalloped, or cut-in wings expanded three inches across, we can but wonder at the secret of the change which went on silently in the buried chrysalis. The wings are a beautiful ash color,

FIG. 61. UNDER SIDE OF CHRYSALIS.

with a faint reddish tinge; the fore wings ornamented with two very rich dark velvety-brown spots nearly square in shape, and the hinder

wings are of a bright pink, bordered behind with ash color. There are also two triangular brown spots, of the same color as those on the fore wings, on the thorax. He is a very quiet moth, resting for hours in one position, and not at all vain, as he takes no pains to show his chief beauty, the exquisitely colored hinder wings, which are almost entirely covered by the front ones. Thus far he has not been seen to uncoil his tongue, though tempted by sugared water on moss and flowers, and, last and chiefest, by a leaf-cluster from his own vines, which "give forth so sweet a smell" that if he had any reminiscences of his former life, he would, one might imagine, be induced to prove himself still entitled to the name *Philampelus*.

XIX.

THE FOX-FACED MOTH. [ADONETA SPINULOIDES].

FIG. 62.

ONE more look at the little round, smooth chrysalis, not larger than a pea, which has been watched carefully since last August, and lo! standing meekly by its open house is the delicately fringed, bronze-shaded moth (April 14, 1882) so long waited for. It is one of the limacodes, so difficult to bring through from caterpillar to imago. Once before (December 2, 1881) one of this kind, a male, came out, but before it could be identified it was so broken, in removing to a new box, after mounting, as to be unrecognizable, so

far as determining its species was concerned. On the 17th of August, 1880, the first caterpillars I had ever seen of this moth, except one, the year before, which soon died, were found on a small plum-tree in the garden (the same from which the first was taken), and they were found now in large numbers. Twenty-two were secured that day, and in a note-book of that date are simply described thus: "They have three or four diamonds on the back—three purple diamonds, on a yellow ground; the rest of the caterpillar is green."

Three days after, August 20th, is noted: "Three of the diamond caterpillars have spun up. The cocoons are small and hard, smooth and parchment-like, and each is glued to a leaf of plum. One is yet unchanged on the leaf. These were under a tumbler. The rest were in a glass box, which being ribbon-bound and not perfectly tight at the side, allowed a few to escape. Two were found and put back, so that there were fifteen or sixteen left. They are very handsome under a microscope. They are pea-green and spined down the edges at the sides. There are eleven pairs of spines, fringed with delicate black hairs. The three pairs in front, and the three pairs behind, are larger than the intermediate ones. The

spines are scarlet, and each one branched with five smaller spines, which are pea-green. The diamonds on the back run into each other ; three toward the head and two toward the back, and, under the microscope, there is much work on these diamond-shaped spots. There are three straps across each one of the larger diamonds, and these are buttoned at either end of the strap.

“The space between the diamonds on the back (which space the microscope reveals, although to the eye alone they appear to join) is yellow.”

Again under date of August 24th : “The fourth of the diamond-backed caterpillars spun up. A small, round cocoon, smooth like the rest, but pea-green instead of brown.”

At length, there were more than a dozen of these small chrysalids, but of them all only one reached the imago state, and appeared as early as December 2d, as mentioned above. Its description, carefully written at the time, is given December 3d :

“It is of a rich brown and light drab. Characteristics : Large black eyes, low down in the head ; a hairy crown-like tuft, rather square and flat on the top of the head, which is dark brown, edged with light drab ; legs slender and

silvery ; thighs large and spined ; no tongue visible." After he was ready to mount, and so was quiet enough, I counted the joints of the antennæ with a microscope and found them about thirty-six. The front of the head seemed pointed and nose-like. On each side of the nose, just over the eyes, are the antennæ, amber-colored. They start from almost the same point. This peculiar shape of the head gives it a fox-like appearance, and having been struck with this, I was pleased when a friend noticed it, and remarked : "It would be strange if he should show fox-like habits." The legs are very slender, and in both the specimens I have had, seemed to come off very easily at the first joint—once from being caught in a drop of sugared water the leg was left in the sweet, and with no gain to the mouth, as there was no notice taken of food. After losing his leg (the right front one), he would use one of the antennæ in its place, and turn the other back to edge his left wing !

August 22, 1881, two more of these bright little caterpillars were found, and the next day one more. These were on the same plum-tree, and although several other plums were near, no trace of one has ever been found on

any of them. These three were all that could be found last year, and in a day or two, two of these were covered with little ichneumon rice-cases. So that but one cocoon was made, and this, fortunately, survived and came out in April; so much later than the other moth of last year, that it had almost been given up. The case in which the moth was enclosed, inside of the cocoon, came out of the cocoon, a clear skin, showing all the marks of the moth, even the antennæ. There were six eggs fastened upon the leaf in two exact rows—amber colored. These being on the under side of the leaf, were put into the cyanide jar, unnoticed, and thus probably had their life destroyed. Whether the egg-life will survive that which killed the moth, will be an interesting question. The markings of this moth are not so distinct as of the male one, and the body is somewhat larger. The colors are similar, although the contrasts in shading are less marked.

XX.

LIFE IN A BASKET.

IN a recent number of a magazine a correspondent asks, "Can any one name a caterpillar which lives on evergreen trees? It carries its cocoon on its back. The cocoons have evergreen needles hanging down the sides."

This curious caterpillar, usually called Basket-worm, from its basket-like case, belongs to the Psychadæ family. On the 5th of August, 1879, I received some of these curious baskets, from a friend in New Jersey. The baskets were bottle-shaped, rough, and covered lengthwise, with bits of arbor-vitæ. One was drawn up close at the neck like a sack—(the Germans call them sack-trager or sack-bearers) and I supposed, as it was perfectly still, that it was dead, or had changed to a chrysalis. Another at once put out its head, and the three following rings of its body, and began to walk up

the glass box (ten or twelve inches high), drawing his basket along with him, and so walked to the top, and across one end clinging by the ribbon binding. The same day he began to fasten a thread about the stem of a sycamore leaf which I had placed in the box (as, when found, these baskets were suspended by a thread several feet long, from a sycamore branch near an arbor-vitæ). He worked at this thread from five in the afternoon until ten in the evening, making it as strong as possible, as if to challenge a second disturbance. Then he drew up the neck and kept quiet. Now and then, the basket would shake, and swell out to its fullest capacity. About nine in the evening, I noticed the one which I had supposed dead moving. With sharp scissors I carefully cut off the very edge of the closed neck. In about five minutes I saw him draw it gently together. On the 7th, one of them pushed his cast-off skin through the case, when I concluded that he was changed to a chrysalis. But no, a little later the same day, he put out a fresh head and shoulders from the bottom of his sack, shook off the skin which had not been quite freed before, and peered about him ! Then he retired, drew up the opening, as a lady would her work-bag, and, as a caterpillar

I saw him no more. Fresh hemlock, pine, and arbor-vitæ laid close to his basket seemed no temptation to him to undraw those little strings, and by closest watching I could not see that he ate again after the change. The basket would occasionally whirl violently, and then remain perfectly still. Five segments were the most it ever showed. The first three rings back of the head are shelly in appearance. In color it is a grayish-olive, mottled with white, something like a tortoise shell. The mouth and feet are an amber brown. On August 13th, I looked within one basket and found a very dark chrysalis. It was quick in its motions, as was the caterpillar and also the moth. On September 14th, two of the chrysalides pushed out from the basket and in less than half a minute with a little bustling whirr the moths were out. They were black with clear wings, which were shorter than their long tapering bodies, giving them a very curious appearance. The female is wingless, as the *Orgyia*; white with an amber-colored head, and would scarcely be recognized as a moth. The antennæ of the male are doubly feathered. Their basket home is soft-lined and the neck both without and within is free from sticks and soft as plush

to the touch. The female moth never leaves her home. This evergreen Basket-worm is doubtless the species *Oiketicus*, of Harris (p. 415) and which he says "is common in the vicinity of Philadelphia on the arbor-vitæ, larch, and hemlock." I found them this year on evergreens at Ocean Grove.

XXI.

A BLACKBERRY LOOPER.

ON July 17, 1884, I secured from a blackberry a very curious "looper" caterpillar. He was of a mulberry-brown color mottled and ringed, and his body shagreened. He had two pair of hind prop feet, and three pair of true feet in front. His head looked like a double hoof of a cow's foot. If he had been a gymnast or acrobat his fortune would have been assured. Any man who could stand with his feet against a tree, in a perfectly rigid horizontal position, an hour at a time, without moving, might well attract a crowd at a dollar an hour.

This gymnast exhibited free, and astonished you by the wonderful variety of his exploits, and stoical immovability from his position when taken. Now he was a stem to the blackberry. Again a handle to it. Then a syphon; again an "eye" waiting for the corresponding

hook. Then a loop-and-link, as if he had begun to make a chain, and gave out on the second link. Then he made a stiff bridge from one berry to another.

FIG. 63. DIFFERENT POSITIONS OF THE BLACKBERRY LOOPER.

Each of his true feet is armed with an amber claw. The mouth also is amber-colored and yellow. It is difficult to see it, even with the microscope, as it appears as if drawn into its body, or neck, when not in use.

His little group of eyes, or ocelli, are plain to be seen, and he would peer forward in response to my watching, as much as to say :

“ I have as much of an inquiring mind as you ! ”

On July 26th the looper changed to a buff-colored chrysalis, very pointed at the end and having a dark-brown central line (interrupted) down the back.

On August 10th the chrysalis opened, and out came a most delicate pea-green moth, with white wavy bands on fore and hind wings, both of which were fringed. The body is a creamy, silvery white, the head and feet light amber. The legs are spined, one spine on each. The plumed, amber-colored antennæ are broad at the base and taper to a point. The eyes are *large* and of a sage-green color, with a dark circular ring, which appears like a pupil, near the centre, and which under a microscope gives you the feeling of being looked on with a responsive gaze.

The moth has been identified for me by Professor Lintner, as the *Nemoria chloroleucaria* (Gueneé), and is said to be distributed over the United States from Canada to Texas, and is no doubt far better known in its perfect state than as a blackberry-loving caterpillar.

XXII.

THE DRYOCAMPA IMPERIALIS.

HEARING a slight noise in my room one evening, I turned to look at the chestnut brown chrysalis I had long been watching, of the beautiful moth *Dryocampa imperialis*. Having lost the caterpillar of this moth the year before in making its change, I was very glad to see this fine chrysalis (which had afterward been sent me by a friend) at last show signs of opening. This was the first of May, 1880. As I looked a slight parting appeared exactly in the centre of the front of the head, giving a glimpse of the yellow color of the moth. The quickness of the parting and closing of this narrow thread-line, showing the rich golden yellow for an instant, was like the play of miniature "heat lightning." Watching it until after midnight, the chrysalis at last became perfectly motionless, and I left it, thinking it would not move again. To my

FIG. 64. THE DRYOCAMPA IMPERIALIS.

surprise, the next morning there was the same flashing of the little yellow line, which continued without any gain throughout that day, and half of the day following. Thinking it would not be able to break the thick shell, with a fine needle I carefully broke off some tiny bits from the side of the crack, and soon, with a mighty stir and bustle, the moth walked out. But alas, never to shake out the rich purple and yellow wings! Whether he would have finally succeeded in freeing himself from the chrysalis alone, or not, it is certain my assistance did him no service, and the beauty that "might have been," and which was partially revealed by the imperfect moth, only added to my second disappointment. The next summer I received a fine specimen of the caterpillar, from a friend who had found it on its favorite button-wood. I had, scarcely time, after placing it upon a box of earth, to note carefully its sage-green color, reddish-tinged back, orange head and feet, white, green-bordered spiracles, and the six yellow, black-spined knobs on each of the wings except the first, before it worked itself rapidly out of sight, to make its change in the ground.

When the box was being opened the dinner-bell proved, for once, an unwelcome sound,

but thinking (and wisely as the event proved) that *now* was the best time to secure him, I seized my pencil and made the following sketch before satisfying my appetite.

On my return from the dinner-table the surface of earth in my box was marked by a half-circular ridge, about the width of the caterpillar's body; it had gone from sight to make its wonderful change. This it did successfully, and having slept itself into its spring suit (in which matter caterpillars have greatly the advantage of us), it came out of its prison in May, in its exquisite robe of yellow and purple, and with as much ease and celerity as if its ring-notched case was not to be thought of as an obstruction, when it was ready to give me its full-dress surprise.

FIG. 65. CATERPILLAR OF DRYOCAMPA IMPERIALIS.

This large caterpillar feeds upon the Sycamore, and is found during August and September. Some of them are over three inches in length. They are of a peculiar shade of

green, in some cases with a faint reddish flush, and occasionally a more rusty olive-brown. The feet are orange-colored, the spiracles double-bordered with white and green. On the second and third rings are two knob-like horns curved backwards, of a bright yellow—the three pieces, shaped like a triangle at the end of the body are also yellow-edged, sprinkled with small dots of orange-colored knobs, and on each of the rings are six thorned yellow knobs. There are a few thin hairs scattered over the body, but so sparsely as to be scarcely noticeable.

He is a gentle caterpillar, like the *Polyphemus*, but much more difficult to carry through its changes successfully. One which was given me by a friend, the past summer (August, 1889), failed to complete his change into the chrysalis, although every care was taken that he might do so. He had been brought a long distance, and possibly received some injury by the way. This caterpillar is rare, certainly in Pennsylvania—and about as difficult to secure in an afternoon search, as is that of the Royal Walnut. I have as yet never been so fortunate as to find one, although sundry protracted peerings into the leafy boughs of the Sycamore on many a ramble may have

suggested to an on-looker the thought that he had encountered some one not very remotely connected with Zaccheus. Probably the easiest way to obtain them will be found through the egg, by securing the moth itself. In the capture of a moth one should not lose this possibility of a bonanza by "*jarring*" them *at once*, in order to secure a "perfect specimen." This thought came to me just in time to save my putting a fine female Luna moth into the cyanide jar as soon as caught, when, had I done so, I should never have been able to record my "Barrel Full of Lunas."

XXIII.

A BARREL FULL OF LUNAS.

ON June 22, 1883, a beautiful Luna moth was given me by a friend. It was the first living moth of this kind I had had, never having been so fortunate as to secure the caterpillar or its cocoon. Just as I was about putting it in the cyanide jar, the thought struck me that I might possibly secure eggs and raise moths of this beautiful species. Scarcely had I decided to keep it, before I noticed a cluster of eggs on the inside cover of the box in which it was brought to me. Here was a treasure indeed. And, in three days after, there were over thirty eggs in the box. They were dark brown, a little smaller than those of the Polyphemus, and biscuit-shaped like them, each having also a slight central depression. Most of them were lying in the form of a chain, in an almost regular connected line. On the second of July many of

FIG. 66. ATTACUS LUNA MOTH.

the eggs hatched, the young caterpillars being a light pea-green, a little less than an inch long. The spines were in clusters, like those of the *Io Saturnia*, those on the back having a purplish tinge. They began to eat fresh walnut leaves at once. In a day or two, little beaded knobs began to show, running lengthwise in rows. Some, which had moulted, had rich purple tufts on them,—four on the two front rings (two on each) and *one* on the last ring. The true feet were also purple, or purplish brown. The Luna caterpillars are easily kept. When the glass cover is removed they do not rush to get away, but eat on contentedly. They betray no snappishness like the tomato-worm. When the next change was made, the rows of crimson or garnet spots were much larger. Each crimson spot has a light-yellow border and a little tuft of hair from its centre. The true feet are dark-crimson—the false ones puffy and pea-green, like the body, and bordered at the clasping-edge with crimson. The head is green, marked on the front with crimson, and the mouth is crimson-tipped. When about to moult, the caterpillar fastened itself to the side of the glass by a netting of fine silken threads, head downward and bent forward, the true feet drawn to-

gether, exactly evenly, in pairs, giving it a meek look, as if it were in the act of petitioning for pity. It changed in about two days. It was curious to watch these caterpillars eat, holding a leaf firmly with the three pairs of true feet, and supporting itself by the four pairs of prop feet, with their dull purple or crimson sucker-like claspers clinging to the stem. The leaf melts away before their rapid cutting in a marvellous manner. The amber-like spinnerets stand outside, and the jaws work together sideways, the edge of the leaf being guided by passing between two feelers which hold it steadily in position as it disappears beneath. When the worm was older, the crimson buttons were shaded on the top to light pink. The eight spiracles or breathing-holes at the sides are shaded crimson (a puffed line of yellow-green bordering them), running lengthwise, and cut into lengths by each ring. In the centre of each puff is a crimson dot. When fully grown, the head is sea-green, as also the V-shaped spot on the tail, which is bordered with yellow, and ends with a brown clasper foot, yellow-edged. The true feet are black. The mouth is very elaborate. With a microscope and a good stock of patience, the exact number of these spots of crimson, which

so adorn the Luna caterpillar, were counted. On the first ring, there are six ; on the second, eight ; on the third, eight ; on the fourth, fifth, sixth, seventh, eighth, ninth and tenth rings, six each ; five on the eleventh, and four on the last ring, making seventy-five in all. They are larger than the same beautifully-colored points on the Polyphemus caterpillar.

On the 21st of July, just as they were almost ready to spin up, I was ready to leave on a vacation of at least a fortnight. Two or three on that day had begun to make cocoons, but several, a good deal smaller, must eat some days longer. No one was to remain in the house, and, what was to be done ? To lose twenty or thirty Luna moths was not to be thought of. Had they been canaries, a friend could have been asked to take them in charge. But even the superior beauty of the crimson-bedecked caterpillar might not bring it into sufficient favor to secure the granting of such a request. The problem was happily solved. Ten of them were taken, in a wire box, on the journey, and as walnut trees are not abundant in the part of Massachusetts whither my way tended, an extempore *silo* was made by pressing very closely a quantity of fresh leaves in a tight tin box. This lasted the ten travellers,

and they each made a perfect cocoon against the sides of the box. But for those left behind? A clean barrel was secured. This was papered inside and out with newspapers. Then a large glass jar was filled with water, and long sprays, freshly cut, of walnut were placed in the jar, and this put in the barrel. Then the caterpillars were at home, and by covering the top of the barrel with a rather fine wire sieve, they had plenty of air, and were *kept* at home.

In about three weeks the well-formed cocoons in the travelling wire box began to open, much to my surprise, as I had supposed they were to remain until spring. Reaching home soon after, it was no small pleasure to find not only the cocoons but several moths already out. The contents of the barrel were examined with no little interest, as well as a glass shade which covered some which had been placed under that with a bottle of water filled with leaves. The moths in a few instances had broken their wings, but many were still perfect. They were perhaps a little smaller, but not less handsome, for their rather cramping experience. Very few had died, and there were still some leaves left not altogether shrivelled.

The Luna moth is of exquisite form, and delicate colors. It is a light pea-green, with edges bordered with yellow, and a brown edge to each fore wing. It is tailed, and has two handsome transparent centred eye-spots, of white, black, yellow, and a faint tint of red. Those of the hinder wings are round, and those on the fore wings are like an inverted comma. The body is white and covered with a soft, fine wool, the antennæ yellow and plumed, and the legs a purple brown. The colors in the eye-spots are so blended as scarcely to be separately distinguished without a glass, the whole appearing like shades of brownish pink.

The cocoon is made much as that of the Polyphemus, but is not attached so firmly to the stem or branch. The experiment of raising them is simple, and of special interest whether done at home or abroad.

FIG. 67. COCOON OF *ATTACUS LUNA* MOTH.

XXIV.

THE FEBRUARY BUTTERFLY. [PAPILIO CRESPHONTES].

A LITTLE fluttering noise as I passed, last February, a shelf where chrysalids are kept under glass, revealed a spring, or, rather, *winter* "opening." The first butterfly to appear from among the many housed sleepers was from a chrysalis long and carefully watched, and which came out February 21, 1884. It was the Cresphontes butterfly, and should be a large and handsome one, but, alas! from some unknown reason, he appeared with sadly crumpled hinder wings.

If one has an unusually long chase for a butterfly he has never had before, and breaks his wings in taking him, it is disappointment enough; but to wait, without even the excitement of a chase, from November 15th to February 21st following, and then have an imperfect one, seems almost too bad. How-

ever, here he is, and wide awake, and, so far as perfect, handsome. And "life" shall be made for him as nearly "worth living" as possible. In fact, he looks as if he thought it were, now, as he uncoils his long, black, three-grooved tongue, and sucks the sweetened water from the beautiful cups of creeping evergreen (*pyxidantha barbulata*), which seemed to come from the South to-day on purpose to give this Southern butterfly a welcome. At any rate, not more than half an hour after he left his cell, the postman left the box of "moss" which came from Wilmington, N. C., and its beauty and sweetness *must* atone for his poor, folded-up wings. He sips eagerly, and raises his front wings and sways his long, over thirty-jointed or ringed antennæ to express his satisfaction. The *Cresphontes* is, when of full size, with wings spread, from four to five inches across. He resembles the *Turnus* butterfly in color and form, but the markings are different. I have seen but two—the handsomer of these in the Lenox Academy Museum, last summer, and one which flew into a friend's house, on College Hill, Easton, Pa. These caterpillars, for I had three of them last fall, are very curious, and entirely different in appearance, in that form of their life, from

FIG. 68. *PAPILIO CRESHONTES*.

the Turnus. They were found on a prickly-ash tree in the grounds near where the butterfly above named was caught. They ate the leaves of the prickly-ash, but did not seem very fond of it. In reading what I could find of the Cresphontes, I learned that in Florida it lives upon the foliage of the orange tree, which is, I then noticed, classed in the same family with the prickly-ash. (See Gray's "School and Field Book of Botany," p. 81 Rue Family.)

So, thinking they might prefer orange to prickly-ash, I obtained sprays of leaves from an orange tree in a friend's conservatory, but they turned from it with contempt, as much as to say, "I know in what locality I am, and if I can't have my native air, I will not accept my native leaf." And here I must mention a fact noticed several times with much interest. It may not always hold, but has, I believe, in each case that I have watched. The caterpillar that is said to like several kinds of leaves, will *prefer* the kind on which it first found itself and began to feed upon. The *Saturnia Io*, found upon the corn blade, refused the dogwood leaf, which it is said to like; and a Polyphemus, found on an oak, in Massachusetts, turned away from the maple every time,

although those found on the maple ate that greedily. No doubt, rather than starve, they would take some of the other kinds which they are said to eat, although I think the *Cresphontes* would have starved sooner than touch the orange leaves. The description of the caterpillar I quote from my butterfly journal, written with the living specimens before me.

“Oct. 15, 1883.—The shape of the *Cresphontes* caterpillar is very curious, and the colors rich and velvety. It is hooded, the hood covering much of the time its small, olive-green head. The hood is ornamented with round rings (of white or russet), four round rings on the front edge and ten on the lower edge. One of the three (smaller than the others) has a moist, slimy look, and the rings look more like little clear bubbles than well-defined circles. There are six lavender-colored, irregularly-regular spots on the back, just above the white and bulging end. The sides are grayish-green. With a microscope, the rings show beautifully, and one wonders at the amount of exact work in so small a space. The olive-green head has a white line, which runs straight down the centre a little way, and parts in a delta. It has a pair of

crimson horns, which do not show except when disturbed. The true feet are a clear, light olive-green, — the false feet grayish-green, fringed with white hairs, marked and mottled with small crescents.

“Oct. 16th.—One of the *Cresphontes* spun a few threads, and attached himself to the side of the glass box to change his coat. His head is small and black, and is meekly bent against the glass, not in sight, looking from above.

“Oct. 17th.—The *Cresphontes* keeps perfectly still against the glass. Watching him carefully with a microscope, I cannot see the least movement, more than if he were dead.

“Oct. 19th.—The *Cresphontes* still fixed against the glass. With the microscope I saw a most minute insect (not half so large as a period on this page), on his head, which annoyed him. Brushing it off with a feather, he threw out his crimson horns, and revealed well where they protruded. From a horizontal slit on the forehead (an almost imperceptible line), both issued from one opening, being joined at the base, in one short, crimson stem, which is close to the angular top of the head. I had doubted whether he could use these, having been so long suspended for his change; but he did, readily.”

At length the *Cresphontes* died, after leaving the glass, and soon both the others died. A friend then gave me a perfect chrysalis, formed at the same time, and which yielded the crumpled butterfly. The wings are jet-black above, with an irregular band of almost golden-yellow spots on the upper pair. The hind wings are bordered with yellow some distance from the scalloped and tailed edges.

FIG. 69. CHRYSALIS OF CRESPHONTES CATERPILLAR.

The chrysalis is much like that of the *Turnus* in shape, and is suspended, like that, by a silken thread around the body.

Having sent the above sketch of my *Cresphontes* to a paper, it was noticed by a lady in Florida where this caterpillar is a well-known devourer of the orange foliage, and where there are often four broods during the year.

She very kindly sent me a box of the butterflies, so large and beautiful that I was well repaid for the disappointment my poor deformed specimen had given me. The common name in Florida for this caterpillar is "the orange dog," from a fancied resemblance of its most curious head to that animal. When in its native home the caterpillar is much

FIG. 70. THE CRESFONTES CATERPILLAR.

larger than the specimens I had obtained from the prickly-ash, in Pennsylvania, where it was evidently a new comer, and not to be found at its best. In Florida it is found nearly three inches in length. The gray and brown caterpillar, after feeding for a month, changes to the chrysalis, and after a sleep of from one to

two weeks appears in the beautiful bright-winged *Cresphontes* butterfly. Its dull colors are said to resemble the bark of the orange tree so exactly as to make it difficult to be found, except upon close examination, a good example of the safety afforded to many insects by this conformity of color to their exposed places of living, while in a helpless state. When winged they can afford to triumph in the safety of flight, fearless of colors of a brilliant hue.

Since writing the above I have seen, by a report of an Ohio entomologist, the "prickly-ash" given as the "food plant of the *Cresphontes*" in that State.—[March, 1890.]

XXV.

A THOUSAND TO ONE.

TO every caterpillar its own secret. It can keep it well, but not forever,—truth will out at last. I can almost imagine one of them laughing at your surprise, as, after day by day you have carefully taken long walks to provide its special food, and watched it spin its patiently-wrought silken house, you look for the imago of the moth or butterfly you have “studied up,” to appear, and, lo! instead, a company of buzzing intruders—five, ten, twenty, a hundred ichneumon-flies (*Copidosoma truncatellum*). No little suspicious-looking rice grains, even, carried around on its back (such as some caterpillars bear, to hint of disappointment beforehand), were to be seen on the back of the pale-green caterpillar secured from a stalk of wild-lettuce on the 24th of October. It was a fine-looking specimen of *Plusia brassicæ*; and, as it was so late

in the season getting ready for its change, special care had to be taken to select from among the already dying leaves of lettuce enough unwithered ones to satisfy it at its daily meals. However, as this was but for four days after its capture, it was done ; and then it mounted to the top of its glass prison, curled itself into the shape of a letter S, and began to spin threads of silvery-white silk back and forth around it, completing the covering while it was yet thin enough to disclose its zig-zag outline beneath the web. It was delicate pea-green in color, having two pale straw-colored stripes running down each side of a line of pea-green in the middle of the back, while on each side of this was a line of still brighter yellow, and each of the rings was so constricted as to occasion a corded appearance. The head was pea-green, like the body, with a small russet spot on each side. There were but two pairs of "false feet" (beside the prop-feet at the end) ; so, of course, it was rather an unusually strange "looper." Under a microscope the stripes appeared wavy, like watered silk ; and irregularly scattered over its body were tiny white dots, many of them bearing a short bristly hair, not to be seen except with the microscope. It was

about an inch and a half long, tapering toward the head; and this, with the curious shapes it assumed when walking or feeding, made it an interesting object to study. Sometimes it would lie straight along the stem, but, if disturbed, would quickly loop itself, and stay in its bent posture until reassured.

FIG. 71. THE CABBAGE PLUSIA, *PLUSIA BRASSICÆ*: *a*, THE LARVA; *b*, THE PUPA WITHIN THE COCOON; *c*, THE MALE MOTH.

We waited until November 18th for the change, when we should see, instead of a striped, halting, looper caterpillar, coiled up in his silvery hammock, a beautiful tufted moth. A curious change came, indeed, but far more so than we had anticipated. At the "opening" that November morning, no gray-

yellow-and-silver-winged creature appeared, as we surely had a right to expect, but instead, under the glass, fully one thousand brilliant tiny ichneumon flies. With black heads and iridescent wings (a shade of turquoise blue prevailing), this busy little cloud of intruders darkened and brightened the glass prison. In the first surprise of the moment the glass was lifted a very little, when dozens escaped around the edge. These were instantly brushed into a place of safety, and the rest secured by replacing the glass. The caterpillar's secret was out, and the task he had left for me was—counting. For who that has not seen it, is going to believe that from one caterpillar (after he has lived out his first stage of life, and built his resting-place for the next two) there should spring, as I have asserted, a thousand other lives? So, after several days, when all the busy, darting gleaming rainbow specks were forever still, I took off the glass, put them on a white paper, and with the point of my penknife moved them off in groups of tens and hundreds, and, besides all that had at first escaped, there were by actual count eight hundred and thirty-two.

In looking up all I could find about this *Plusia brassicae* moth (for I had seen only the

figure of it), I was interested especially in one fact given in a number of the *American Entomologist* (1880), viz., that this caterpillar is a veritable cannibal, and is quite ready, if its legitimate meal of lettuce, cabbage, or turnip be not at hand, to make a dinner off a neighboring caterpillar of a different family, and even to threaten the same unkindly office to one of its own. If the little ichneumon-fly has happened to note this propensity, it has surely had ample satisfaction in the way of revenge.

The caterpillar of the *Plusia* is a great robber when found in abundance, as in many places, eating cabbage, lettuce, tomato, turnip, and especially celery. It has been a great annoyance in Washington city. So in Eastern Pennsylvania we may congratulate ourselves if they are so scarce as to prove, in a single case, a treasure to the entomologist.

XXVI.

THE COMPLAINT OF THE CHRYSALIS.

THEY are in such a terrible hurry
To see what I 'm going to be !
I 've heard them all talking it over
But I fear that they never will see.

They took me from out my dark chamber,¹
Where the light strikes me now all the day ;
And if I don't move then they push me,
To see if I 've died by the way !

As soon as my wings get some color
And begin just a little to show,
Beneath my poor helpless brown cover
What is hidden they 're crazy to know !

Dame Nature, my kindest of mothers,
I *hope* she will see me safe through,
But I tell you she will not be hurried,
Whatever impatience may do !

¹ The *cocoon* is often opened without harm to its enclosed chrysalis, that the changes of the latter may be noticed as it approaches the imago.

If you only would leave me in darkness,
 In quiet and silence to rest,
 I 'd burst on you some pleasant morning
 In perfection of beauty full dressed.

But I think that last touch on my shoulder
 Has injured a delicate wing,
 And I tremble to think of your waiting
 To welcome a poor blighted thing.

I should like just the chance once to show you
 How lovely a moth can appear
 Who has slept undisturbed in his casket
 His little two-thirds of a year.

XXVII.

THE TUSOCK MOTH.

I HAVE been trying to-day to feed a moth, or to find whether he has a tongue. Hearing a slight rustling noise coming from a shelf

where the sleepers in several tufted felt-like cocoons had

FIG. 72. HICKORY TUSOCK CATERPILLAR. been taking their long winter naps. I looked to see if it were possible that any of them had been cheated by the unusually mild weather into the belief that Spring had come. Sure enough under two different glasses fluttered, this January day (Jan. 11,

1880), two buff-and-white spotted Tussock moths, wide awake and ready for flowers,

FIG. 73. HICKORY TUSOCK MOTH.

while snow covered the bare branches of the hickory trees, where their first life was spent. Looking at the date on the paper with the label, I find that the larger of the two moths, (which are alike), was found, a full grown caterpillar, in the previous autumn, September 13, 1879. Turning to this date in my Butterfly Diary, I find he was a yellowish-olive-green caterpillar, with yellow brush-like tufts on his back, a pencil of white hairs on each side of the first ring, a pencil of dark hairs on each side of the second ring, and two black pencils from the last ring. All the feet, "true" and "false," were of a clear amber hue. The head was jetty-black, with small white spots at the mouth. This caterpillar draws down the white pencils of the first ring so as to veil the whole head, which makes the two dark or black pencils of the second ring stand out like horns. The first ring has a few small oblong yellow spots upon it. When disturbed it instantly rolls into a round button-like coil, remaining for some time perfectly still. When all danger seems past, it as suddenly starts from its pretended sleep, and walks rapidly as far as its prison will allow.

The caterpillar of the second moth was found on September 16th, three days later

than the first. He was a pale lemon-yellow color, with an amber-colored head. Although I see no difference, upon the most careful examination, the caterpillars were thus slightly different in color. The four pencils in front, of the second caterpillar, were of a deep orange color. There were back of these two pairs of shorter white pencils, and the two from the last ring were also white. The tufts (like small square cushions) on the back, spring each from a black-dotted centre. The whole caterpillar has a soft and very neat appearance. The feet of this one were white instead of amber color. I have since raised many of these caterpillars and find that they vary in color, some being mouse-colored, some yellow, others gray, and others olive-green, and often those of one of these colors, on changing his coat will be found to go from gray to lemon-yellow, or from olive-green to drab, and yet the imagos or moths will all be of the same color, which is the exact shade of the hickory-nut meat, (a yellowish-brown), sprinkled with white dots. It is a quiet, gentle caterpillar after it once yields to its imprisonment, as a fixed fact. Until then it is unceasing in its efforts to find its freedom.

The cocoons of the Tussock moth caterpil-

lars are made entirely from their own hairs. They are oval, as shown in the cut, and take, of course, the color of the caterpillar in its last stage. Of the eight or ten now waiting in their chrysalis state (December, 1889), some are gray, some brown, and some of a delicate purplish hue, but all will yield the hickory-nut-meat moth. Some of them are suspended from the top of the glass, while others lie on the paper at the bottom of the box. They differ in size, the largest being an inch in length. The opening at the end of the cocoon where the moth makes its escape is so small as not to be noticed at the first glance. I said I had been trying to find whether this moth had

FIG. 74. COCOON OF THE
HICKORY TUSSOCK MOTH.

a tongue. If he had it was not to be tempted from its covert by sweets, to which, even when dropped upon his mouth, he paid not the slightest regard. In fact, he is proving that he would rather die than eat, as he is now, after several days' entire abstinence, very nearly through his quiet little life.

Many of the Tussock moths described above came out in January. This year (March, 1890) not one cocoon has yet given up its

pretty moth, although the caterpillars of the more than a dozen now waited for "spun up" quite as early last fall as did those which appeared in January. Just twenty moths of the *Saturnia Io* have come out in the same "chrysalis room" during the first half of this month, and the last two weeks of February, as well as two Polyphemus moths and two or three other kinds, quite throwing the promptness of the Tussock moths, this year, into the shade. But

"They will not be hurried,
Whatever impatience may do."

XXVIII.

WINGED AND WINGLESS.

“**I**N natural history nothing is small.” This truth often strikes one when they direct the microscope to a little speck, hardly sure but that it may prove a grain of sand, to find a perfect insect, beautiful in form and adorning.

There is no caterpillar (perhaps with one exception) more handsome, to me, than a quite

FIG. 75. FEMALE (WINGLESS) OF
ORGYIA LEUCOSTIGMA.

FIG. 76. ORGYIA LEUCOSTIGMA
MOTH.

common one found on the maple, or willow, and often on the rose leaves, in the early summer. (And here I may note that, lest I should not *fully* appreciate its beauty, and also that I

might understand the value of a worthy setting, one of these caterpillars walked slowly over the satin crown of a lady's hat, immediately in front of me in church one Sabbath morning, a perfect picture of beauty, while the haste with which it was brushed from its well-selected promenade ground by one who saw in it "only a caterpillar," proved that in some eyes the "setting" may be of more value than the gem.)

This caterpillar is not a very small one after all, being an inch or a little more in length ; but a microscope is needed to reveal fully its many special points of beauty. Of the several which I have tried to watch through their caterpillar life into the perfect imago, I have but one left, and for fear he too

will die, with his caterpillar frock on, I will give his portrait with my pencil, although you may have brushed him from you hastily, after many a summer ramble, unstudied and ignorant of his beauty. He is one inch in length, and his prevailing color is a delicate but bright lemon-yellow. This forms a fine groundwork for touches of peculiar beauty.

FIG. 77. CHRYSALIS AND FEMALE MOTH OF ORGYIA LEUCOSTIGMA.

His head is a pale coral-red. His small mouth jet-black. The top of his head and his sides are covered and fringed with a few soft straw-colored hairs ; those of the head, bending forward, giving the coral the appearance of being shaded with yellow. If he were not so restless it would be more easy to give an exact description of him. Moving his tufts of hair backward and forward, it is about as easy to count his twelve rings as to count a long train of cars, in good motion.

FIG. 78. CATERPILLAR OF THE *ORGYIA LEUCOSTIGMA*.

From the first ring there springs a long wavy pencil-plume, just back of the coral head ; a brush of black hairs, shingled in sets of two or three different lengths, and each of these hairs feathered like an arrow at the tip. From the fourth, fifth, sixth, and seventh rings, there rises a very full, thick, even brush of soft yellow hairs, like four miniature oblong clothes-

brushes, laid one after another along his back. On the top of the eighth ring is a flat spot of a beautiful crimson color, while the ninth and tenth rings have each a little crimson ball upon their top. From the centre of the eleventh ring, rises another beautiful pencilled plume, and the twelfth is finished with a delicate fringe of fine brown hairs.

Like other caterpillars he changes his coat three or four times. The long plumes coming off with the discarded coat, while new, fresh, and longer ones are ready at once to take their place. After wondering, while watching this change, how long it would take for these shingled plumes to grow, after the old ones were thrown off, what was my surprise to see them slowly rise up, fully formed and handsomer than those laid aside a moment before!

He is a very restless caterpillar, and probably his dislike to imprisonment is the reason he so often fails to reach the chrysalis state. The one whose picture was taken above, died, but another, a fine specimen, was soon obtained, and placed in a larger glass box—one nearly a foot square. Here, with plenty of food—rose leaves and horse-chestnut leaves, (of which they are very fond also), he seemed content, and grew finely. Being ready to leave

home for a fortnight's absence, I placed a large bottle of water in the box and put a branch of maple in it, judging this would afford him tolerably fresh food as long as he would wish to eat. Returning from my visit, and going to see how the prisoner was getting on, lo! he was gone. The maple leaves, however, had been pretty thoroughly devoured, and thinking he might possibly have pressed his slender body between one of the ribbon-bound and rather lightly fastened sides of the box, I searched thoroughly for the little truant. The box stood upon a mantel, above which hung a heavily framed portrait. This was taken down and lo, on the back, in one corner of the frame, was a small, very thin, and odd-looking chrysalis. It was gray in color, and formed of hair, with little rough spots upon the sides and top. The plummy pencils had gone to form the cocoon! Not many days after, there was a small opening in one end of the cocoon, and on its top was a clear white glassy looking, or frothy appearing, substance which looked something like a few crushed glass beads dropped in glittering pinches upon the gray cocoon. Presiding over this mass, (of what was really a cluster of eggs, covered with a frothy substance), was the queerest little apol-

ogy for a moth! "Can this be all, after all my watching?" I said. I thought it an unfinished bit of Nature's work—a deformity, and had well-nigh brushed the whole away in my haste, when lo! a pretty little stranger moth flew by me, hovering near the chrysalis. *This*, I thought, might after all, be the true moth from my handsome caterpillar, and I determined to prove it. Confining him, I kept watch for another caterpillar, and was fortunate enough to secure two or three large specimens; and, in their transformation to find, first, another of the queer, almost wingless, whitish moths, *and*, also, two, the exact mates of the pretty gray-winged one I had before caught and still held a prisoner. Winged, and wingless! The upper pair of wings to this male moth were banded with wavy lines of a darker, ashen-gray, and had a small black spot near the tip of each wing, with a very small crescent of white near the outer edge. The back of the moth was tufted handsomely, but all of ashen-gray. No hint of scarlet, coral, or crimson. The glassy frosted eggs again appeared by the wingless moth (who never left them), on the cocoon's top, and opened at length to release minute specimens of my coral-headed, pencilled-plumed caterpillars. These,

11

not being noticed soon enough to receive their rose-leaf meals, soon lived out their little lives, but not until I had taken the caterpillar of the *Orgyia Leucostigma* safely through its little round of insect life. Certainly the beauty, in his case, lies in the first stage of his existence; although the gray-banded crescent-marked *Orgyia* has a quiet beauty not to be overlooked.

XXIX.

A RACE FOR LIFE.

NOT between man and man and not between animals, but between a plant and an insect. "The gooseberries look splendidly this year. I do not believe that they will be attacked by the persistent little enemies that ruined them last year."

A day or two after this cheering prophecy last spring another examination of the flourishing bushes revealed the unmistakable enemy in full force. On May 16th, three of them

FIG. 79.

were brought in and put under glass. The next day two threw off their coats and the third soon after, although eating up to the last moment, as is their greedy way. As every thing was early last year, so these false caterpillars were some days earlier than the year before. On May 20th of that year, they were fast putting on their last coats. Some were put under glass on that day and carefully watched. They had jet-black heads. The first ring back of the head was yellow, and there was a yellowish ring near the tail. The rest was a bluish-green, and the whole spotted thickly with black dots looking like little irregular drops of black sealing-wax. The feet were black. In crawling over the leaves one came near impaling himself on a thorn. He held back his head, sphinx-like, and considered the matter carefully, concluding to take the leaf and give the thorn a wide berth.

The next day (May 21st) one of these changed his coat and came out in a pretty and more spring-like suit of soft pea-green. He has the advantage of the leopard, for not a spot is to be seen on his new attire. The yellow bands are there as before, but not a vestige of black. The head is yellow, and the next two rings a brighter yellow, and also the third from the

last and the last rings. The feet are also a very light clear green, almost colorless.

Keeping a close watch on the second it was easy to see him change his coat, which he accomplished in about five minutes. The head was first freed, and the old coat slipped back, aided by constant movements of the head and the fore part of the body already freed. He was ready to eat a fresh meal almost as soon as he was released.

After he changed his coat he spun a small yellow silk cocoon, almost transparent, drawing over a notched lobe of the leaf, half hiding it from sight. Whether it would come out a moth or a butterfly I was uncertain, having then never seen a description of this caterpillar. He did neither. On the third of June he came out a fly, with four transparent, netted wings, black head, and yellow body, with seven-jointed antennæ. There are some black spots just back of the head. There is bronze-like gloss

FIG. 80. CURRANT SAW-FLY.

to the clear, pretty wings, the legs are bright yellow, and the tips of the toes black. A careless observer would not think of his

being more than an ordinary house-fly dressed up a little for an afternoon call. Surprised at the shortness of the life of this caterpillar, I thought it strange they should be able to destroy the gooseberry leaves so completely.

FIG. 81. CURRANT LEAF EATEN IN CIRCULAR HOLES
BY THE SAW-FLY.

The caterpillars soon seemed to be all gone ; again the gooseberries threw out fresh young leaves and seemed determined to get the upper hand, but their triumph was short. Very soon

the new leaves were bordered with the unmistakable black-spotted rim, a second brood left the bushes bare, and not being satisfied with their full meal adjourned, by way of dessert, to the current bushes where, after a short stay, their little cast-off dotted coats could be seen all over the twigs and their yellow heads busy making small crescents in the currant-leaves. Not long after, their cocoons were spun and they were snugly stowed away to await the new leaves of another spring.

There are some kinds of caterpillars, and these are among the number, which birds avoid, and so if any one is to come to the rescue of the gooseberries it must not be left to them. But after watching them through all the windings and changes of their curious little lives, and forgiving them for robbing me two years in succession of gooseberry tarts and currant pie, I will leave this part of the matter to certain books where the secret of their extermination may be found. According to one of these books, they have been in this country since 1860, when they were imported from Europe into nurseries in Rochester, New York, and are known by the name of "The Imported Currant Saw Fly."

XXX.

THE BULRUSH CATERPILLAR.

AMONG the most curious productions of New Zealand is the singular plant (called by the natives *Awheto*), the *Sphaeria Robertsia*, or bulrush caterpillar. If Nature ever takes revenges, one might imagine this to be a case of retaliation. Caterpillars live upon plants, devouring not only leaves, but bark, fruit, pith, root, and seeds ; in short, every form of vegetable life is drawn upon by these voracious robbers. And here come a little seed that seems to say : "Turn about is fair play," and lodges on the wrinkled neck of the caterpillar, just at the time when he, satisfied with his thefts in the vegetable kingdom, goes out of sight, to change into a chrysalis and sleep his way into a new dress and a new life. A vain hope. The seed has the situation. It sends forth its tiny green stem, draws its life from the caterpillar, and not only sends up its little shoot

with the bulrush-stem capped with a tiny cat-tail, but fills with its root the entire body of its victim, changing it into a white pith-like vegetable substance. This, however, preserves the exact shape of the caterpillar. It is nut-like in substance, and is eaten by the natives with great relish.

A friend who has recently spent some months in New Zealand brought me the specimen, a drawing of which is here shown.

There are other cases of this vegetable retaliation, but none so curious as this of the bulrush caterpillar. The larva of the May beetle is attacked by a fungus which grows out of the sides of its head ; but while this growth destroys the life of the larva, it does not change the larva into a vegetable substance.

A near relation of the murdered caterpillar is the larva of the New Zealand swift moth, upon whose tapering head sometimes appears a similar growth,

FIG. 82.

which feeds upon the life-blood of the caterpillar until it dies from exhaustion.

A very curious sight must be one of these heavily-burdened crawlers moving along with the banner that announces its doom solemnly floating above it. For, when the young cater-

FIG. 83. LARVÆ OF THE NEW ZEALAND SWIFT MOTH.

pillar bears this growth upon its head, it heralds the slow but certain death of the overloaded insect.

A transformation as curious, perhaps, in an opposite direction, is that of the insect *Drilus*,

which, in its larva state, lives upon the snail—animal life drawn from animal, instead of vegetable, substance. This beetle larva, with its sucker-like feet, attaches itself to the shell of the snail, watches its opportunity, and slips inside. It lives upon the snail (sometimes using three snails before changing to the chrysalis state), and then, after it has finished its last meal, it closes the door of the last shell, and sleeps into its winged life. If insects think us cruel in putting out their little lives rather roughly, or if they complain that sometimes revengeful seeds change them into miniature “caterpillars of salt,” as it were,

Just let them study how they treat each other,
And learn more tenderness each for his brother ;
How innocent the small ant-lion,—sleeping
Beneath his pit of sand, while slowly creeping

Upon its edge a little ant comes near him,—
Then quickly, ere the ant has time to fear him,
Seizes his prey (the small deceitful sinner !)
With no compunction, for his stolen dinner !

The dragon-fly, in gauzy lace, and airy,
Sailing about like some delightful fairy,
Cares he what beauties butterflies embellish ?
He darts upon, and eats them with a relish !

In spite of all, if cruel still they style us,
 Just let them think upon the thieving *Drilus*,
 Who helix-back is very fond of riding.
 And also into neighbors' homes of gliding.

And takes his meals without thanks to the donor,
 Sleeps in his house and lives upon its owner.
 Three rides he takes, three little homes up-breaking ;
 Of three poor snails three travelling-pantries making.

A fortnight lives in each, the third one keeping
 Quite to himself, at last ; and soundly sleeping,
 Waits for his change—new life in some fair garden ;
 But quite too late to ask the poor snail's pardon !

The singular change in this curious caterpillar is thus described by the friend who brought me the above specimen, Rev. J. W. Walker of Liverpool, and presented by Mr. S. J. Capper, President of the Lancashire and Cheshire Entomological Society at a meeting of their society :

“This singular arrangement comes to pass in the following fashion. When the caterpillar buries itself in the ground to pass into the chrysalis stage, the minute spores of the fungus find lodgment in the neck plates of the caterpillar. There they vegetate, and strike root inside the horny case of the animal, living on its tissues. The animal dies, forming simply a root for this plant, which thus

lives on flesh. The bulrush attains a length of about ten inches, its apex, in a state of fructification, resembling the common club-headed bulrush of our own ditches. When fresh, these plants taste like a nut, and are eaten by the natives, who also burn them and use them for tattooing. When newly dug up, the caterpillar's body is soft, and on being divided longitudinally the intestinal channel is plainly seen. The vegetating process commences during the life of the caterpillar, for decomposition has not set in, nor is the skin expanded or contracted in any way. This forms one of the most extraordinary freaks of nature in the connection between animal and vegetable, and is perhaps unequalled in the annals of biology."

XXXI.

A BEADED CATERPILLAR.

A VERY pretty, small, smooth caterpillar was given me last fall, September, '88, found on some flowers of a bouquet, so that its special food could not be identified. A few days later, I was fortunate enough to find one like it upon a spray of golden-rod. These caterpillars were of a *seal-brown* color—all one shade of brown, very velvety in texture, about an inch and a quarter long, and cylindrical; of one size throughout and about one third as large as an ordinary pipe-stem. What was my surprise on looking at the one given me (which I had placed under a glass), half an hour later, to see a very different looking caterpillar. Down each side was a row of white beads, perfectly symmetrical, and of a pure milky or chalky whiteness, globular and about the size of an ordinary pin's head.

Taking a magnifying glass I watched it with

interest. Presently one of the white beads disappeared, then another and another twinkled out, until lo ! the plain seal-brown caterpillar again. Touching it with a little stick, out came a bead here and there, their irregularity giving it a most curious look. I tried the second caterpillar, and it also threw out the chalk beads. I saw they were from the spiracles, but had never seen such a phenomenon before. On writing to Prof. Lintner about them, he replied that he had not observed any thing of the kind. The caterpillars, doubtless, may be found upon the golden-rod, as they ate of this plant and no other, which was tried, but neither of them (probably from having been disturbed too much in order to watch the coming and going of the beads), made a chrysalis. They are now small dried specimens, but remains of the white dots are visible upon them.

A few days since, I was interested in coming across a hint of this kind, found in an old encyclopædia (Rees, Art. "Stigmata"), in the following sentence. Speaking of experiments by Malpighi upon stigmata, he says :

"Mr. Reamer repeated his experiments, and concluded that these apertures served only for the *inspiration* of the air, which the caterpillar

afterwards *expired* through the whole superficies of its body, because he could never observe that any bubbles of air were ever driven out of these stigmata ; but Mr. Bonnet, on the contrary, *having seen bubbles of air* coming out of these openings was led to infer that the *inspired* air was also *respired* or discharged through these same orifices."

Now, if in the case of these two caterpillars, it had been *merely* "bubbles of air," would not the beads have been *glass-like* in clearness, instead of chalk-white ; and could they have remained perfectly globular so long, as some of them did for several minutes ? These questions it would be interesting to have answered, as well as to learn the complete history, in the imago, should any be able to secure a specimen from next autumn's golden-rod.

XXXII.

ATTACUS CYNTHIA.

ON March 21, 1879, I received from a friend in New York a box containing nine cocoons. When I first looked at them I thought they were cocoons of the *Attacus Prometheus*, so much, in all but their size, did they resemble those familiar cocoons, many of which I had watched open in the years before. Like those of the *Prometheus*, the cocoon is made with the leaf on which it feeds drawn partially or entirely about it, and this is securely fastened to the tree stem or branchlet; but often upon so small a stem that this tight winding does little toward the safety of the chrysalis. Many fall from the tree and are blown about, until, as one writer says, "the streets of the cities in which they have become wild are often strewn with such cocoons, which get trodden on and destroyed." On cutting open the cocoon of a few of my nine I found

FIG. 84. *ATTACUS CYNTHIA*: *a*, EGGS; *b*, LARVA; *c*, COCOON; *d*, CHRYSALIS;
e, FEMALE MOTH (after Riley).

the chrysalids of a dark yellowish-brown, and in shape much like those of the Prometheus.

The first of these cocoons gave up its beautiful imago on the 24th of April, giving me a most pleasant surprise in a large moth of great delicacy and beauty of coloring. The body was thick and looked as if made of soft dark cotton with a close dotting of white tufts over it. The under side of the body was white tufted, on a yellowish-colored ground. The wings are of a yellowish-green hue, with variable markings, among which lavender is prominent. There is a crescent upon each wing, and a line of white edged with rose-color running across them gives it a striking and peculiar beauty. The moth varies in the time of waking from its chrysalis sleep, some remaining in their flossy-lined cocoons a much shorter time than others. The first one that came out of those sent me was a little over a month in making its exit.

The next moth of the "nine" came out on June 8th. It was handsomer in shading and colors than the first. The prevailing color was a beautiful shade of olive-green. The four crescents were a very light lavender color with a lower border of white and a yellowish olive-green. Through the centre of each wing

was a wavy band of darker olive-green. But one must *see* to appreciate a moth with so many colors and such varied markings.

One more of the "nine," Cynthia's, came out a perfect moth, but, unfortunately, in attempting to escape in securing his liberty he rushed to his death. How the glass lid of his prison got moved enough for his escape I never knew, but I found him caught and marred (injured so that he died) in the partially-closed window of the room. How he was caught was also a mystery. The only solution that could occur to me being that he alighted on the frame of the sash, and was not noticed by the person who opened the window too suddenly for his attempted escape.

Through care of many other moths, and absence from home, the record ends here. One of these moths was secured from a cocoon given me, on June 20th of the next year, since which time I have not been fortunate enough to secure any.

The Cynthia is a native of Japan and China. It was introduced into France over thirty years ago, and many attempts have been made to use the floss of the cocoon in making silk, which have proved partially successful.

XXXIII.

THE TURNUS BUTTERFLY.

ALTHOUGH the large gayly-colored butterfly, *Papilio turnus*—(as the best American butterfly-knower, Mr. W. H. Edwards, of Coalburgh, W. Va., says), “inhabits all sections of the United States, from the

FIG. 85. CATERPILLAR OF PAPILIO
TURNUS.

Atlantic to the Rocky Mountains, and from Maine to Florida and Texas,” it had never

been my good fortune to meet with one until I saw these flying over the large tulip trees of Eastern Pennsylvania. Their brilliant coloring attracted my attention, but their flight seemed always so high that after many attempts, I gave up the hope of securing one in the ordinary way. Had I known or thought of the caterpillar, or of the tiny egg, with its little silken hammock ready almost as soon as hatched, on

the upper side of a tulip leaf, I could sooner have had possession of what I so much desired. Or had I known that, when attracted by its favorite flowers, the "blossoms of the wild plum," (for which I give it great credit as choosing almost the sweetest flower that blooms), or hovering over beds of phlox, or patches of red clover, it was so lost amid the sweets of its eager meal that it could "be captured with the utmost ease," or that at any given time or place it could possibly have been found so abundant that Mr. Scudder (a very careful and truthful scientist) could assert that "sixty-nine of these butterflies had been caught between the hands at one grasp!" I certainly should not have paid ten cents a piece for two or three broken-winged specimens brought me by a little boy hired to secure the prize for my collection.

However, a broken-winged butterfly, is better than none, and studying from these, their marvellous beauty made me but too glad to learn that the caterpillar lived chiefly upon the tulip-tree leaves, although it did not despise many other varieties of food. Fortunately there were three of these handsome trees at our own door, but I had never seen the butterfly about them. I had only seen it, in long rambles, darting

FIG. 86. PAPILIO TURNUS.

through the upper boughs, (and often above all the boughs) of the tallest tulip-trees on the banks of the Delaware. Now for a search at home. Looking carefully among the lower leaves of the tulip, no egg was to be seen; (it needs a trained eye to see a small egg on a high bough !) but what is this singular looking caterpillar, walking toward me on the pavement near these trees? I capture him and say: "Perhaps he may show me yet my *Papilio turnus*." It was true prophecy. He was a dull looking and curiously marked little fellow, with a figure "10" always plainly marked on about the third ring on each side of his dark brown body, not far from the very large head, and giving him a quaint appearance, as suggestive of an inquiring eye.

My first *Turnus* caterpillar made his chrysalis September 20, 1878. He suspended himself much as the *Asterias* does, with a slender loop supporting him against the side of the box. The chrysalis, also resembles that of the *Asterias*; is a yellowish-brown in color and rough in texture, with his head prolonged in two ear-like points, and a similar projection a little below the head in front. [I have four of these now waiting (March 20, '90) their exit, after a six months' sleep.]

This first chrysalis of '78 opened on March 12, 1879. A large and handsome butterfly, with no rude marks of boy capture marring his perfect sunny wings of bright black and yellow. Since then I have had many such openings, but none ever gave me a more welcome or highly prized Turnus than this. I found a fine caterpillar of this kind in Sing Sing, N. Y., in the summer of '82, and watched it make its chrysalis on the 21st the following September. Another which I studied more carefully a few days later, as he made this change, gave me a two hours' interesting study with the microscope on the evening of the 23d of September. More than once I thought he had died from his perfect stillness after efforts to effect his change. On each side of this caterpillar, I noticed (without the microscope, but very plainly *with* it), three spots of vermilion surrounded by a cluster of brown dots. Another, not yet ready to change, although suspended against the side of the box, had a band of orange-yellow around the third ring. The one with vermilion spots I saw finally throw off his coat as if glad to be rid of it. The first of these chrysalids opened on April 6, 1883. Yellow and black dashed with spots of bright orange. On April 16th, another opened, large

107

and handsome as any yet secured. From two or three of the *Turnis* chrysalids came a curious *Ichneumon* fly.

It is a singular fact that the female of this butterfly in climates warmer than that of Pennsylvania are often almost entirely black. These are described in Mr. Wm. H. Edwards' full account of this butterfly in his beautiful work on "*The Butterflies of North America.*" He speaks of this change of color as "without a strict parallel among butterflies." Another butterfly-collector says that "in Georgia half the females of the *Turnus* are black."

In all that I have seen, the male and female *Turnus* butterflies are yellow and black and very much alike in their appearance.

Why there should be this curious change of color in those of the Southern climates is not satisfactorily accounted for; and although several ingenious "suppositions" have been given it is still left, by the best entomologists among the mysteries which cannot be explained.

186

XXXIV.

THE BEECH-NUT BOX. [LIMACODES SCAPHA.]

(For illustration, see preface.)

IT is said by Harris, in his "Entomological Correspondence," of that most singular genus of moths, the Limacodes, that "they remain a long time in their cocoons, or in earth, before turning to pupæ." To this fact the student of entomology will give a ready assent!

In his larger work, Harris says of this *Limodes scapha*: "My specimens generally died after they had made their cocoon, and, consequently, the moth is unknown to me." Why he should use the word "generally" is a question, when if *one* only had not died, the moth might have been known to him.

By substituting *always* for "generally," my experience with the *Limodes scapha* is told.

Yet there is too much of curious interest in his first and second stage to omit a sketch of what, so far, must be but two thirds of a little life. He has certainly given me enough trouble, by way of watching and waiting, to warrant me in taking so much of his life as I can, especially as it is in a way which he cannot *feel*. He is, as a caterpillar, correctly figured (from a photograph which I had taken of one fine specimen) in the preface, where he is compared to the old-fashioned "beech-nut box." Harris saw rather a likeness to a little boat, and so "named him *scapha* (a skiff)."

As the change to a pupa *usually* takes place within a few days after the caterpillar has made its cocoon, one, before learning that the *Scapha* often remains for months in his little round parchment-like home, before throwing off his caterpillar coat, might easily give him up as dead, and throw away what would have paid for a little longer waiting. This I have done with one or two other kinds of caterpillars, who have the same habit, learning afterward my mistake. Some caterpillars lie in their cocoons through an entire winter, and then change into a chrysalis and finally come out into their perfect state.

In a walk down a shaded lane, in September 1879, I found my first *Limacodes scapha*. It seemed at first uncertain whether it was a raised place in the leaf, from some insect's sting, or something that was alive. I took it home, and, even with a microscope, could hardly determine whether it was animal or vegetable. At last it moved a *little*, not its position, but only a little contraction of the body, keeping almost as still as the leaf throughout the day. After the gas was lighted in the evening, I sat down with my microscope for a good look, and lo! the *Scapha* was just changing his coat. He was very little altered in appearance. He was a delicate pea-green, with a light spot of grayish brown on the top of his back, which slopes up to the centre and down again, like a water-shed. Just before he changed his coat, he puffed up and swelled like a puff-ball. He seems to be stomach-footed, like the saddle worm. He is marked by horizontal cross lines, and there are two triangular spots between each of the two lines before the middle line of his body, and two after it. He puffs out now and then, until he resembles a globe-fish. There are irregular brownish-gray spots on the sides, below a light central line, running

through the centre from the broader front nearly to the apex. Back of the centre or the top, but on the backward slope, are two smaller grayish-brown spots. From 9 A.M. to 8 in the evening he has not changed his position on the sumach leaf, on which he was found. Harris gives the "walnut" as the food of the *Scapha*. This *Scapha* began to eat on the 23d (the day after he changed his coat) from an apple leaf. On October 5th the *Scapha* was very restless. He was now a pale straw color, or more nearly cream color. He walked about softly, looking as if gliding on water, like a little fairy-boat. The two spots on his back, just below the centre, look like two miniature lakes, and the two near the end are pear-shaped. The sides appear as if crimped. There are two small raised points on each side, at the centre line, very curious in appearance, which have showed from the first as a noticeable feature, and suggestive of eyes. I had thought they might be, when a friend, to whom I showed it, asked at once: "Are those little points eyes?" It would be no queerer place for them than the snail has for *his*. His head, for the most part, is entirely out of sight. When he puts it out (as a turtle does from its shell), it

is round, of a light ochre-yellow brown, and has two pairs of feelers, one pair a little shorter than the other.

The Scapha has eight distinct breathing-holes, or spiracles, nearly round, and very dark brown or black, and about the size of a small period in fine print. This description, from my butterfly journal, ends with the true remark: "It seems as if, with a microscope, I might write an hour longer and not tell all his markings."

On October 9th he began to spin a slender cocoon. After beginning a very gossamer-like hammock, he stopped work and remained three days quite still, and eating nothing. More than once I was "sure" he was dead. Then he would move again, slowly rocking his tiny boat from stem to stern. Then he would draw in his head, and seem to be making an effort to change his coat, once going clear over in a funny summersault in the attempt. He was now orange-colored, and shrunken into hills and valleys. Towards evening he crept around to the little floss-silk tent or hammock, which he began and discarded some days before, and attempted to join a few floating threads for his cocoon, although his internal resources must have been limited, as

he had not tasted food for four days! A magnificent example of patience and perseverance, far exceeding that of Bruce's spider, which had the physical strength *with* the patience, while the poor Scapha had to supply both. A good lesson from the little Limacodes, even if the *first* period of his triple life should be all he will ever attain. October 10th and 11th he was still at work, walking up and down and all around his box, working away toward his change. He had earned the right to call this "a changing world"; the only fear was that he would not find it big enough for him to change in!

October 13th.—Such an exhibition of *life* as the Scapha gives is seldom seen. Moving about, yet not having touched a leaf for a week and a half! The last record of him, *alive*, was on October 17th. Then he gave up his tent-working, and soon his struggle for life. Since then I have had several of these Limacodes, and some of them have made a nice plump cocoon, but never yet has one opened. On breaking the cocoon of one, after there was no hope of life about it, I found the shell very similar to that of the egg of a bird. It is nearly round, a dark brown in color, and smooth itself, although usually having a loose

dark flossy substance around it. I have now (March, 1890) three or four well made *Scapha* cocoons, and the wish to see them give up the imago is in due proportion to the interest with which its caterpillar life has been watched. Although Harris had failed to see the imago, and many others have had the same experience, it has been safely brought through its changes, and Packard has given the

FIG. 87. SCAPHA MOTH.

figure of the perfect insect, from which the moth here is taken, in his "Guide to the Study of Insects," p. 290. He says of the moth: "It is light cinnamon brown, with a dark tan-colored triangular spot, lined externally with *silver*, which is continued along the costa" (or outer edge of the wing) "to the base of the wing, and terminates sharply on the apex." A living proof, with its silver finish, that *riches* will still "take to themselves wings, and fly away."

A little after finishing the above sketch (March 28, 1890), to my very pleasant surprise, I found under a glass in the chrysalis room *my first* *Limacodes* moth! He had stolen a march upon me at last, and, without observation, had shaken out his wings of

"silver and cinnamon brown," lived his brief life (without the welcome and attention that would have been gladly given), and fallen asleep on the floor of his little prison; his empty brown cocoon and its little round lid lying beside him. He is, however, a prize in himself, and a herald of hope for the four still unopened brown balls, for which he has secured a closer watch for their possible opening.

XXXV.

THE MONKEY-FACED MOTH.

OF all the *curious* caterpillars it has been my good fortune to see, the palm, for sheer oddity, may be given to that of the Hag Moth. On September 18, 1883, this curious brown caterpillar was given me by a friend, taken from a cherry- or apple-tree. It is brown in color,

FIG. 88. THE "MONKEY-FACED" MOTH. HAG MOTH (PHOBETRON PITHECIUM)

very nearly the shade of an almond meat. It is rough in appearance and most singular in form. It was a study to find at which end of him was the head, for, like that of the "saddle worm" (*Empretia stimulea*) and that of the

Limacodes scapha, to which genus he also belongs, his head is out of sight, under the first ring. There are three singular appendages, flanges or fins they might be called, on each side, as shown in the sketch of him above. The appearance of this "flange" is much like one of the points of a star-fish, even upon close examination, and there is the same little blackish round-dot finish at the base of each, or where it joins the body. Upon examination with the microscope there is to be seen a double row of starry spines (eight on each side) down the top of the back, but so fine (while yet perfect stars) and so exactly the color of the rest of the body as *only* to be noticed with the microscope. Just under the upper surface of the caterpillar (so as not to be seen from looking at it above) there is a row of smaller-sized stars extending around the entire body. Had this been noticed by the entomologist who gave him his name he might have had a prettier one than that chosen from his homeliest feature. For myself I shall call him the Hidden-Star Caterpillar. He is like the *Scapha* in his movements, gliding along the leaf with a slow, graceful motion; and if disturbed, he puts down his head on to the leaf, bending over and making a low

brown bridge of himself. His head is small, amber-color in the centre and dark-brown on either side. He stands on the side or edge of the leaf to eat, bending his head over the leaf so that you cannot see him eat, except by looking on the under side of the leaf. He eats the cherry-leaf readily, and, although his motion seems slow, he goes very soon from one end of the long leaf to the other. It is a difficult thing to see him eat, even when you know by the melting away of the leaf that he is taking a meal, and have also your microscope well adjusted for observation. This is because his mouth is so protected by a fleshy half-hood on each side that you can only see the crescent he cuts growing larger, and his head (wherever it is!) moving along to meet new demands of his cherry-leaf. I have watched the same thing in the "Saddle" caterpillar; his fleshy hood sucks down upon the leaf and hides his mouth entirely.

On the 23d of September, five days after he was given to me, he *began* to throw off his flanges—not all at once, but gradually, one on the 23d and the next on the 26th. On the *edge* of most of these flanges, near the end, there are two small black hairs with little black knobs, like tiny pins stuck in, and from this

point they seem to break off most easily. On the 26th, after losing off two flanges, he fastened himself between two leaves preparatory to making his cocoon. On the 28th the hard, almost round, blackish-brown cocoon was finished, in size and shape as given above, and, strangely enough, having its flanges stuck around it by way of ornamentation! I had *read* of this curious habit of the Hag Moth before, and could scarcely believe it possible that he could pick up and attach these appendages to his cocoon after it seemed finished. But "seeing is believing," and there they surely were, and evidently as firmly fixed to the little ball as they had formerly been to his body. I should have seen *how* this was done, at the risk of disturbing him in his cherry-leaf covering, had he not stolen a march on me when I "was busy here and there," and so kept his secret a mystery still.

Watching was now over, and, except to label him in his glass prison, he might be forgotten until the winter was over and gone. Yes, and the *spring* also. On the 5th of June the lid of the little brown house was thrown back a very little, and out stepped this very pretty moth after nearly a ten-months' sleep. He flies quickly from one part of the box to

another, or walks with his funny twinkling feet rapidly up the glass, a contrast as surprising to the slow-motioned caterpillar as is the handsome coat he now wears to the rough brown jacket of his caterpillar days. So far as I could see, or prove by tempting sweets, I could not find that he had a tongue. Perhaps he might have found it himself had he been free to fly from honey-cup to honey-cup of real out-door flowers. Yet I think if he had been very hungry and had any means of supplying his need, he would not have scorned the sugared moss that seemed to have no attraction for him. True to his first and second stages, he is still *brown*, but handsomely *shaded*, making so much of the *different* shades of his favorite color as to give him a very handsome dress. The principal color is almost a seal-brown (a few shades lighter), and the front wings marked with dashes or spots of a light yellow-brown, with a wavy band of the same color crossing them; a spot of still lighter brown marks the centre, and the edges of the wings are a shade of still darker and very rich reddish-brown. His beauty can only be really known under the microscope, which brings out a richness of coloring and beauty of arrangement that redeems the Hag Moth from any

suggestion of homeliness by his most unfortunate and inappropriate name. When he came out from his brown cocoon the skin of the pupa, clear as crystal and perfect in shape throughout, came with him, and lies now by his side in his little box, and the lid of the cocoon flew back so exactly in place that to-day one might look at it carefully and think it a perfect, unbroken chrysalis. Besides the six flanges described, there were also six miniature ones, which scarcely showed beside the longer curved ones, but which, like them, fell off, and were, in part, at least, attached to the little brown cocoon. Just twelve in all, now safe beside the cocoon, the pupa case, and perfect insect. All that is wanting is the triple row of stars, but by one who has once seen them he will be still remembered as the *Hidden-Star Moth*.

XXXVI.

THE 'SMARTWEED CATERPILLAR.

ON the 25th of May, 1878, a bright-colored caterpillar, which I had found on the smartweed, made a cocoon. It was very thin, and of an almost glass-like material, except that the *top* was ornamented by fifteen or twenty of the little knobs of the pink blossoms on which it had been feeding. The cocoon was boat-shaped, and the chrysalis inside was a rich, shiny light brown, tapering from the head to a very pointed end.

The moth came out on June 14th, after about three weeks from his change to a chrysalis. He is very delicate in coloring, without a trace of the rich hues he wore as a caterpillar. The upper wings are a bright silvery white, dotted slightly with dark gray, the edges rounded, and delicately finished with narrow white fringe, just above which is a row of tiny black dots, each at the end of a crimped line

or fold. The under wings are silvery-white in fluted folds, with no color except a row of very minute black dots above their beautiful silver-fringed finish. The body is ringed with alternate silvery-white and brownish-black dashes

FIG. 89. THE SMARTWEED CATERPILLAR.

on a white ground. The antennæ are long, not feathered, and slightly curled at the end. The joints of the feet next the body are broadly feathered, but slender to the foot itself—looking like a child's arm in a short puffed sleeve.

The caterpillar of this moth, as I have said, is very gayly colored. The head is jet black, with a few yellowish-white bristly hairs falling forward from it and from the first (black) ring. The second ring and all the rest but the last two have on them six reddish-brown little knobs, with yellow radiating spines, with two short white lines below each circle of spines. The first ring has two short white lines, the first one of the two interrupted or broken in the middle $\text{--}\text{--}$ and the second whole ; on the second ring this is exactly reversed, the first line whole and the second broken $\text{--}\text{--}$, and the third is the same ; all the rest are broken and more irregular. On the last two rings there is only a white line. A scalloped line of bright gamboge yellow runs down each side of the caterpillar, and little dashes of yellow here and there over another line of white. The reddish-brown knobs are on a velvety-black ground, giving the whole a very rich appearance. The under part is a dark-brown. Sometimes the cocoon is like thin white silk and almost transparent. The nearest description answering to what I have only known as the "Smartweed Caterpillar," is the *Apatela oblinita*, or, as it is sometimes called, "The Smeared Dagger."

Both the caterpillar and moth very nearly answer to this description, the greatest difference being the transformation, as one writer gives it, "occurring in the ground." I have often raised the moth from the caterpillar and never seen any variation in the form of its cocoon, until a most singular experience last September, which has given me a *rare* "specimen" indeed. A caterpillar from the Smartweed, to all appearance the same as above described, was secured and placed in a glass box. To my surprise, when the time came for his change, instead of spinning his thin cocoon he went up the side of the glass and fastened himself in exact imitation of the *Asterias* or *Turnus* butterfly, by a slender thread, with no hint of a cocoon! Here he stayed, not throwing off his skin; but keeping his position so long that I was led to examine carefully into his case. What was my surprise to find that he had changed into a white substance closely resembling chalk. The *head* retained its natural color, being even brighter than before. All the rest was hard and white throughout. Where had the brilliant colors gone? He now sleeps in a gilt box on a bed of pink cotton, a curiosity as well as a *lesson*, for what words could so plainly emphasize the truth that in giving up our own

natural way of living in the attempt to imitate others, we shall neither become like them nor keep our own identity, and only remain fit specimens for lovers of the grotesque to place in their cabinet of curiosities.

XXXVII.

THE GREAT LEOPARD MOTH.

ON the 4th of October, 1884, I received from a friend in Orlando, Florida, a handsome, quite large moth, and a large number of eggs which were laid in the box after its capture in the pine woods. The moth was white and covered with black rings and ovals. Its body on the upper part was yellow, with rich and very dark bronze-blue spots on the back and sides, while the under part was white, with black dots to match the upper wings. The hinder wings were white, with a few irregular black spots on the border. The moth was about two inches across. It was left a day or two in the box before sending, and my friend, on looking at it before mailing, wrote: "As the 'white owl' in the box was so still I said, 'If he is dead I'll send him,' and when I looked, what a sight met my eyes! Hundreds of turquoises in layers—in tiers—

FIG. 90. THE GREAT LEOPARD MOTH. [SCRIBONIA].
a, FEMALE; *b*, MALE.

FIG. 91. CATERPILLAR OF LEOPARD MOTH (CURLED UP LIKE A CHESTNUT BURR).

and now you can have plenty of white owls. But what shall they be fed with? As they were found in the pine woods, possibly on the Blackjack oak leaves." A part of the "turquoises" were sent to Professor Lintner, who kindly identified them, and gave as their food plants, plantain, wild sunflower, and willow, with one or two other varieties of plants. He pronounced them eggs of "The Great Leopard Moth," *Scribonia*, which is "the largest of the American Arctians." Two days after receiving them (on the 6th of October) the little caterpillars came out in hosts, and readily ate plantain leaves, making fine lace-work of the leaf, eating only the parenchyma. At first they were about $\frac{1}{12}$ of an inch long, amber colored alternating with dark brown. A brown head and one brown ring, next; then two clear amber rings, and three brown with one amber at the end. Long black and white hairs (about evenly divided) were scattered sparsely over the body. They would not eat oak or any other leaves with which I tried them, except mallows, which they ate as readily as plantain. On the 27th of October they were about an inch in length, growing very slowly, and changing to a rust-red color after the first month.

On November 3d I gathered a quantity of plaintain, now difficult to find, and made a "silo" by packing it closely in a glass jar, hoping it would last them until they "spun up." It was a vain hope. The ice and sleet and snow of late November covered all the "green things growing," and still the Scribonias lived and still craved food. On November 25th I succeeded in getting enough mallows and catnip to last a few days. But soon this was gone and more snow came and still they lived on! They had had six moults, and where was it all to end? A supply of spinach from the grocers, while it was to be had, took them into December. Now and then in some shaded nook a little mallows could be found, even a small "basket-full" is recorded for the 8th of December. On December 9th I "made over a dozen little cornucopias and placed in their boxes to entice them to go into chrysalids!" But caterpillars will not be "hurried" any more than chrysalids, and still they ate on! Christmas came and went, deep snows followed, the old year went out and the new came in, and *still* the Scribonias lived on. I became discouraged and had about given them up to *time and fate* when a card from Professor Lintner, on Janu-

ary 10th, announced the arrival of two fine Great Leopard Moths. Again I attempted to satisfy them with cabbage leaf, and as a last resort ("necessity being the mother of invention") they were fed on apples, sliced so thin as to make them think it was *leaves* with which they were supplied. On the 29th of January the first *Scribonia* chrysalis was made. On the 30th there were seven chrysalids; on the 31st, eleven. On the 11th of February I watched one of the caterpillars change into the chrysalis. It took a little over an hour before the heavy brown coat, with its crimson bands, was thrown off, and the plain brown chrysalis was still.

When these caterpillars had reached their last moult I was surprised to find that I had once had two specimens of the same, found in Pennsylvania (Easton). *They* lived a long time, but finally seemed so stupid and still they were given up as useless, and thrown away. No doubt had "patience" with them had its "perfect work" I should much sooner have known the beautiful Great Leopard Moth. They were very similar to the common brown and black caterpillar of the *Arctia Isabella* or *Isabella* tiger-moth, but about twice the size, and on close looking showing a

bright crimson line marking each ring. Harris says of it : " It has been confidently reported to me that the Great Leopard Moth has been seen in Brookline, but it must be very rare here for I have never heard of its being taken in any part of New England. Specimens of this fine insect would be a very acceptable addition to any collection of such objects." I thought I fully understood that last remark ! I understood it better on *March 4th*, when after all the watching and waiting two fine specimens of the Great Leopard Moth stepped from their chrysalids, and were at once named " Cleveland " and " Hendricks," in spite of my politics, in honor of the two successful candidates, who after an equally long struggle were inaugurated on that day ! After this it grew to be no surprise as one after another left their brown cases until all had made their exit, and " specimens " were at a discount ; although the beauty of the moths paid, after all, for the very leisurely way in which they chose to give this " very acceptable addition " to our collection.

FIG. 92. THE EUDAMUS TITYRUS.

XXXVIII.

A BUTTERFLY CHASE.

ON the 24th of August, 1881, a very singular caterpillar was given me. He was of a pale yellow-green color, with a large red head, on each side of which were two round bright-yellow spots, giving him the appearance of looking at you with very big eyes. The spiracles were small, and black, and the feet orange color. His habits were as peculiar as his looks. He kept closely to the under side of the wistaria leaf on which he fed, although this caterpillar likes the wild bean equally well. He even fastened himself slightly to the leaf by spinning a few threads, to secure him more effectually from prying eyes. But as he ate of the leaf, in nearly circular holes (from near its centre), I could watch the movements of his head from above, yet could not see him actually eating. I

watched in vain for this, and came near starving him, by deciding that he did not want food, until I learned his secret, which was that he ate *only* in the night. I kept him until August 31st, when, in some mysterious manner, he slipped the moorings to his leaf, and managed also to get out of his glass prison, and I saw *him* no more. But the *first* lesson was secure. In September (5th), 1887, during a woods-ramble, I found another caterpillar of this kind upon a wild bean (the *Wistaria frutescens*). His red head, with the large yellow spots like eyes, quickly led me to know him. His neck seems set in his head, like a cork in a bottle, only that it turns easily, and reminds one of the neck of a toy needle-box bird. Under the microscope the head is rough, like the rind of a cantelope. He, too, ate only at night. A few hours after I had secured him, on looking at him his head seemed a clear amber- (glass-like) yellow, but on close examination it proved to be only the *old shell of the head*, not detached, but pushed forward, and soon it fell upon the bottom of the box, the new head looking brighter than ever, and very soon the old coat followed, and all was fresh and new. *So* far he got, but failed to make a chrysalis! In May, 1888, four

chrysalids were given me by a friend. What they were was not known. They were a dull yellowish-brown in color, very full-bodied, the four or five rings at the end having a screw-like appearance, and looking on the entire surface, with its fine crinkles, like "crackle-ware." On the 26th of May I heard a little rattling noise from one of the four chrysalids, and soon two small black eyes appeared at an opening on the back, just below the head. It was an *Ichneumon* fly, and the tough chrysalis gave him work enough to pay for his robbery. He thrust out a pair of antennæ, and unrolled an amber tongue, and took sweetened water from his chrysalis-case prison, much to my amusement. He did not succeed in freeing himself until the next day, when I broke a small bit of the case, when he walked out, and about the box, a russet-brown fly, with a black head, smoke-colored wings, black antennæ, with one bar of honey-yellow across them. The under body was yellow, two light lemon-yellow spots on the thorax. The thighs were russet-yellow. He was about the size of an ordinary wasp, and a Beau Brummell for polishing and pluming. What the other three chrysalids held was still a mystery. On June 3d, a week after this *Ichneumon* appeared,

the second chrysalis opened. I had been out to drive that afternoon, and as we came near a wild plum-tree we saw a very pretty butterfly darting among its flowers, and then across the road like a flash, and back again. The carriage was stopped, and I eagerly watched the efforts of one more successful in butterfly capture by hand than any one I know to secure him, but in vain. Your hand was upon him just as he was on the other side of the road! Securing some branches of the sweet blossoms, I was arranging them in a vase on my return, on the table where the three chrysalids were lying, when the second chrysalis opened, and out came the very butterfly we had failed to secure in our afternoon's chase! The wild plum-blossoms were ready for him! The next one gave also a fine butterfly; and one never opened. And this was the way I learned the whole history of the beautiful *Eudamus Tityrus*.* I have the two specimens and the Ichneumon now before me, the only ones I have ever secured. The butterfly is so swift in motion, with such

* The *Eudamus Tityrus*, one of the *Hesperians*, or *Skippers*, is the largest of the butterflies in that large group, which seems almost like a connecting link between moths and butterflies, their chrysalids being shaped like those of moths (conical in form), while the antennæ are hooked at the end, as are those of the sphinges.

a darting, zigzag dash that it is next to impossible to catch him in flight. His wings are a rich velvety-brown, with a golden-edged, interrupted, honey-yellow band across the middle of the upper pair; and lighter honey-yellow spots (almost in small squares) are found near their tip. The hinder wings have a very short, rounded tail, and a broad band of silver glistens on the middle part of their under side. The antennæ are turned back at the end like a hook. The body is a rich purplish-brown, and the wings are finished with a shaded brown fringe.

TITYRUS.

FIG. 94.

CHRYSALIS OF EUDAMUS.

FIG. 95. WHITE-LINED MORNING SPHINX.

XXXIX.

TWO SIDES TO A SHIELD. THE WHITE-LINED
MORNING SPHINX. [DEILEPHILA LINEATA.]

THE first caterpillar of the White-Lined Morning Sphinx, which I obtained on September 3, 1881, gave me my first lesson in the great variation there often is in larvæ of the same moth. The one I had secured had three stripes down the back, made up of shaded, bead-like spots, strung on a line of pink, with a black line each side of the pink one. He was very dark, had a sharp horn on the end of his body, and spiracles black, edged with yellow. His photograph is given on p. 221.

I had seen this caterpillar in Professor Riley's "Third Annual Missouri Report," as I thought, and turned to page 141 to compare my caterpillar with the figure given there. To my surprise and disappointment, at a hasty glance I decided that they could not be the same. In too much haste to read the text, I was just about closing the pamphlet when my eye caught the words: "The most common form of this larva is given at Fig. 61." The next thought, "perhaps he gives *another* form," led me to turn the leaf, and lo! there was my caterpillar, without a shadow of doubt, in Fig. 62. Then every word of his beautiful description was carefully read. He says: "Few persons are aware what this beautiful moth looks like or what it feeds upon, in the caterpillar state. . . . The very great diversity of form and habits to be found amongst the larvæ of our butterflies and moths has much to do with the interest which attaches to the study of these masked forms. I am moved to admiration and wonder as thoroughly to-day as in early boyhood every time I contemplate that within each of these varied and fantastic caterpillars . . . is locked up the future butterfly or moth, which is destined, fairy-like, to ride the air on its

gauzy wings, so totally unlike its former self. Verily the metamorphoses of the lower animals must prove a never-failing source of joy and felicity to those who have learned to open the pages of the great Book of Nature." *Joy and felicity*, the very words for me, and every new specimen served to emphasize them. He then adds: "The White-Lined Morning Sphinx presents one of the most striking cases of larval variation," asserting that from these very differently marked larvæ the moths reared from them "show no differences whatever."

To *prove* this, which was not doubted, was a pleasant task. My specimen went into the box of earth prepared for him on September 7th, and on rolling back the earth from him September 13th I found him a fine chrysalis.

On the 22d of September I secured another caterpillar of the same kind, and afterward three of the other kind, described in Fig. 61. As these made their several changes to the imago, I found the moths were all alike. On the 24th of May the one I specially watched came out from his chrysalis. He was (very unlike the Polyphemus) less than a minute in coming out! I should not have seen it, but happening to look at the chrysalis at that moment, I heard a slight crackling noise and saw a tremor

or shiver go over the upper part of the long yellowish-brown and pointed chrysalis (where was the head and thorax of the moth). Then the front piece lifted and gave way, and out stepped a thing of marvellous beauty, which had been shut up in darkness and silence in a homely casket since the previous September! The front wings are a beautiful shade of olive-green, with a central line across of interrupted black and white, with a hint of rose or watermelon-heart color. Each side of this, separated by a band of olive about the sixteenth of an inch wide, is a larger, spotted, interrupted line of black and white spots in almost squares, the black a little larger and like velvet, and each side of this is a tint of rose. The beautiful rose-colored under wings unfolded slowly (as did the upper ones in getting their full expansion). The legs are spined and of a delicate mouse color, ending in a minute black claw. The spines on the first pair are very delicate and hair like, and are black. There are two spines of unequal length, almost at right angles, and mouse-color, like the legs, on each side of the other two pairs.

The head is brown-olive in color, dashed with white in stripes running downwards, with

a pinkish-white border finish. The side-protectors of the coiled tongue are so prominent as to look like a front part of the head. The thorax is olive-green with white-dashed lines—one in the centre, then two below it, and a double V-shaped line on either side.

The antennæ are black, bordered on the entire outer edge with white.

The side pieces to the tongue are also white-edged, running back and forming an unbroken line with the head markings. The eye is deep

set, the pupil dark and perfectly round

in the centre of the mouse-colored

wheel-like eye. The tongue shows a little

dark wheel between the side pieces. The

body has a middle line, lengthwise of

interrupted, short, black lines on a soft, mouse-colored ground, and either side of this central line is a row of round black dots, to the end which is very pointed and finished with a pencil of rich brown hairs.

The antennæ in shape look like small bean

FIG. 96.

Pods. They are crossed by regular lines. The centre a chocolate color, with a finely-toothed white edge. Both pairs of wings are elegantly fringed with white. He is swift in motion and when disturbed makes his wings twinkle, as when hovering over a flower. His generic name signifies "Evening Friend," and he is seen to the best advantage when flitting with perfect freedom, like a humming-bird, from flower to flower, sipping sweets with his long tongue and making the most of his new-found higher life.

FIG. 97.

FIG. 98.

XL.

THE "DECEPTIVE" MOTH.

MORE like a very modest, trustworthy Quaker looks the richly mottled silvery-gray moth *Apatela Americana* which stole in upon me on Sabbath, April 20, 1890, from its plain gray parchment-like cocoon;

FIG. 99.

so stiff and hard an one, that in making his exit the whole of the rich brown chrysalis inside it was thrown out into the box beside the clinging moth. Still, demure, quiet, why should it be named "*Apatela—deceptive*"?

Because some entomologists are "strict to mark iniquity," and allow the *moth* to bear the blame of the *first* stage of its existence. For the *Apatela Americano* is an "Owlet" moth, one of the true "Noctuæ" tribe, and yet its caterpillar is so like that of the Arctians as to deceive one versed in entomology, and to lead him to expect either a "great bear" or some other Arctian in the imago. I confess to having been "deceived" by the *very* caterpillar which produced this moth, having bought him of a little boy on August 14, 1889, thinking at the time, "I have had *enough* Arctians, but this one is so bright in *color*, that I will try one more." He was of a fine sulphur-yellow color, and was placed by some light straw-colored Arctians in a box to which little special attention was paid. True he had some long black pencils—two of them on the fourth ring, two on the sixth, and one on the next to the last. But some of the Arctians looked much like him. However, when he began "spinning up" on the 16th, two days later, I soon saw a difference in his *cocoon* and that of the Arctians. Those, instead of being rough and parchment-like and nondescript in shape, are smooth (hairy) and oval—looking as if *evenly* sheared to one exact length throughout.

How long before he changed into a chrysalis inside his rough hammock I could not peer within to see ; but when, after lying perfectly still from August to April, he came out of his hiding place I looked *beyond* the chrysalis to the farther end of the cocoon inside to see if the sulphur-yellow color was visible in the caterpillar robe, which is always folded like a napkin, "in a place by itself,"—and lo ! there it was—the jetty black head and yellow coat, making assurance doubly sure. He now stands quietly under the glass beside me, having satisfied himself with a full meal of sugared water, which I watched him take with his broad flattened, amber-colored tongue. His antennæ are long and slender, have more of a *twisted* than ringed appearance, and are inserted in a little round socket, just above his large dark seal-brown eyes. His body is deeply ringed, and of the same soft brown hue as the wings. These are handsomely shaded, and their borders elegantly fringed, with white intermingled with lines of black. The first pair of legs are ringed with white and black lines and puffed at the top like an old fashioned "mutton-leg" sleeve. The second pair are also ringed but not puffed, and have one small spine. The last pair are plain—neither puffed nor spined.

He is so gentle that the deception of his caterpillar state may be forgiven, and he is no doubt as welcome among his "Owlet" companions as though he started in life in a livery especially his own.

XLI.

THE ROYAL WALNUT MOTH.

“WITH patience wait for it,” were the first words which came into my mind as, in the night of May 5, 1889, a slight tapping noise attracted my attention. On looking in the direction of the sound, I found the stranger, who first knocked and then entered into the world without waiting for a friendly “Come in,” was no other than a beautiful Royal Walnut Moth (*Ceratocampa regalis*). “With patience,” because, for eleven years, I had waited in vain for the perfect imago of this rare and beautiful moth.

The first caterpillar of this species was given me on August 30, 1878. After going through his moultings successfully, and forming at length a perfect chrysalis, he failed to appear, and remained in his casket without power to reveal what “might have been.”

Again and again other specimens were se-

cured, and carefully watched through different changes, but all died before the perfect insects appeared. On September 6, 1888, a fine specimen was given me by a friend; and this, after more than eight months' delay, is now the beautiful *Ceratocampa* before me. Looking back at a record made on September 8th of that year, I find this entry: "Watching my Royal Walnut. He eats silently and rapidly, the walnut-leaf melting away in front of him. He clasps the leaf with his first pair of russet-colored feet, and eats downward, so that his head bends toward the ground. The last two pairs of his long-spined horns lie back gracefully. The first short pair stand forward like ears. The second pair lie across the third, now, as he eats. He eats so as to leave a crescent in the leaf. The long narrow point of the leaf shakes like an aspen as he eats, until he cuts it off and drops it. There are three round black dots on each of the two last pairs of horns on the little yellow part which is next to the head. The three pairs of horns are tipped with black. There are two pairs of horns on the second and third segments. The long point of the walnut-leaf, which he could not eat (being unable to hold it, because it is so delicate), he took with his fore feet, and

lifted it gently out of the way, and then began in a new place."

For the next day the entry is: "The Royal Walnut keeps very still. Has lain for a half hour in the same position—head bent down, so that the first pair of horns rest on the floor of his prison." Upon September 10th, "I gave my Royal Walnut his last meal." At noon he was walking slowly on the earth with which a large box had been filled for him. After an after-dinner nap, I again went to his box. The untasted spray of walnut-leaves lay unwithered on the surface, but no trace of the caterpillar was to be seen. Not a movement of a grain of earth above him. He had buried himself.

After a month had passed, curiosity overcame prudence, and the earth was shaken back to see if a perfect chrysalis was below. "There he lay in his imperfect, half-rounded bed—made by moistening the earth about him,—and as still as if dead."

The chrysalids of many moths will be seen to show frequent signs of life; but the stillest of all still things is the chrysalis of the Royal Walnut. You may watch it for days and weeks, or even watch its shadow, and you will see no slightest movement. The smooth,

plump, black head, with its two slanting breathing-holes, is as still as a rock, and its rings (with the two queer flat little humps on the front one) are as still as the head. Again and again you say: "If there is any life in it, how can it keep so still?" Then you satisfy yourself by stroking it very gently, with the faintest touch of your finger, along the side, and lo, a little cringe, showing the slightest shrinking from the touch. That is all. Again it is as still as a rock. After long watching, another stroke, and another almost imperceptible cringe. It bides its time. So must you.

The eggs of the Royal Walnut closely resemble the Malaga grape in shape and color. They are clear (unlike those of the Luna and Polyphemus moths)—so clear that the larvæ can be seen through the delicate amber shells long before they are broken for exit. At first the caterpillar is nearly black. It changes in appearance, however, with each moulting, at one time being pale-green, again almost a chocolate, and finally a deep dark-green, with pale bands of blue. The ten spined horns with which it is armed give it a menacing and formidable appearance, but it is at all times harmless. It is curious to note the different

expressions used by those who look at it. "Horrible creature!" one exclaims. "It is almost beautiful—so richly shaded," says another. One writer says of this caterpillar: "It is handsomer than the beautiful moth it produces." But, although it has rich colors, curiously shaded, I should say it took some nerve to see the beauty, as the form is certainly unattractive. That from so formidable a creature such an exquisite moth should be produced

FIG. 100. YOUNG CATERPILLAR.

seems little less than a miracle. In color the moth is entirely different from the caterpillar. Its fore wings are of a grayish-olive color, veined with lines of a peculiar shade of red—best described, I should say, as nacarat red. The hinder wings are red, with yellow spots of irregular form in front, and olive-colored spots behind, between the veins. The thorax is yellow, bordered with red. The antennæ, or "feelers," are amber-colored, and in the female specimen which I have, appear to be ringed, when viewed by a microscope.

The moth is gentle and quiet. It takes no notice of offered sweets, and shows no sign of possessing a tongue. For a short time it gives its silent beauty to please, makes provision for other silently beautiful moths (one hundred and twelve eggs were laid by this one), and dies.

The most touching thing in the life of the Royal Walnut is its self-burial. This was carefully watched and timed in one specimen (which, however, failed to develop an *imago*).

FIG. 101. FULL-GROWN CATERPILLAR.

I will close this sketch by a quotation from a record, kept at the time, of two Royal Walnut caterpillars, one of which thus buried itself : " On the 30th of August, 1882, I was fortunate enough to find two specimens of this caterpillar on a large walnut-tree. They were of a mulberry-brown color (probably being in their second stage), with heads of glassy brilliancy ; brown feet, striped with black ; and light, diagonal side stripes separating the spiracles or

breathing pores. Both were watched through their last moultings, and one of them changed into a chrysalis on the surface of the earth in his box. He had taken no food for a week previous, and the opportunity of watching him make the chrysalis was unique and full of interest. He lay upon his back with feet uppermost, and the head of the chrysalis appeared earliest. It was large, and of a delicate pea-green at first. The small, old brown head of the caterpillar is now gliding down very slowly on the top of the newly-formed chrysalis, as it lies on the spined horns below, and looks so

FIG. 102. CHRYSALIS OF ROYAL WALNUT MOTH.

meek and helpless as it is pushed down by the retreating skin. The sides of the chrysalis, as they appear, are tinted with pale red. The spiracles are oval and brown-bordered; the antennæ stand out clear amber. Looking with my microscope, I can see the immature parts of the moth's head arranging themselves; the part where the head is, and inner part of the

vest, not yet being closed. If this space closes over (as it seems to be closed in a perfect chrysalis), it will be very strange to see how it is done. The other Royal caterpillar is eating his leaves contentedly on the walnut branches above him (he is on a spray growing from a bottle of water in his prison), in blissful ignorance of his own coming change."

This chrysalis was not as perfect as those formed underground. That of the second, which buried itself, is the one shown in the picture. The record of its change is under date of September 13th :

"I watched my Royal Walnut bury himself. About half-past eleven A.M., I saw he had done eating, and was very restless, so I put him on a box of earth. It was a touching sight to see him take charge of his own funeral. Slowly he walked around, surveying the ground ; and then, at one corner, chose his lot, and began going down, very slowly, head first, and a little way at a time. He would raise up the back part of his body, nearly vertically, every little while. This earth was fine and mellow, and I thought how difficult it must be for him to go down into the hard ground under the walnut-tree. Nature is wonderful in her workings : Why do the Polyph-

mus, Luna, Cecropia, and Prometheus make cocoons, while the moths of the Grape, Tomato, and Walnut bury themselves in the ground? Why does one never change its *own* way, and try another's plan—some preferring a tomb, and others a burial? Ten minutes past twelve,—forty minutes in all,—and the last speck of green and brown had disappeared. By close watching, with a magnifying glass, I learned a new and wonderful thing. I saw plainly the reason he did not go down faster. He was making a smooth, soft tunnel for himself! He threw from his mouth quantities of water or mucilage, and thus softened and worked the earth, until the whole tunnel was really plastered, and then, by a succession of strong upheavals, he threw the dry earth over the back part of himself (rather than draw that in), until he was hidden from sight. The earth above him trembled and moved for several hours after, as if he was still at work in his burial-place below."

The oval earth-casket which this caterpillar made was much more complete than the one which held the chrysalis of my Royal Walnut Moth. It was probably partly from the gentle breaking of this to get the chrysalis, and from the jarring in taking its likeness given in the

picture, which prevented the appearance of the perfect insect. One who witnesses the wonderful transformation from the creeping, ungainly worm to the exquisitely dainty moth, winged and fitted for a higher life, is reminded of the words of Scripture: "It doth not yet appear what we shall be."

BOOKS FOR THE COUNTRY

THE HOME LIFE OF WILD BIRDS

A New Method of the Study and Photography of Birds.

By FRANCIS HOBART HERRICK, of the Department of Biology, Adelbert College. 4°. With 141 original illustrations from Nature by the author. \$2.50 *net*. By mail, \$2.75.

"Never before have we had placed before us in a series of illustrations from life such a revelation of the intimate daily life of birds in the nesting season as is here presented."—*N. Y. Evening Post*.

BIRD STUDIES

An Account of the Land Birds of Eastern North America.

By WILLIAM E. D. SCOTT. With 166 illustrations from original photographs. 4°. Leather back, gilt top, in a box, *net*, \$5.00.

OUR INSECT FRIENDS AND FOES

How to Collect, Preserve, and Study Them. By BELLE S. CRAGIN. With over 250 illustrations. 12°. \$1.75.

AMONG THE MOTHS AND BUTTERFLIES

By JULIA P. BALLARD. Illustrated. 8°. \$1.50.

THE SHRUBS OF NORTHEASTERN AMERICA

By CHARLES S. NEWHALL. Fully illustrated. 8°. \$1.75.

THE VINES OF NORTHEASTERN AMERICA

By CHARLES S. NEWHALL. Fully illustrated. 8°. \$1.75.

THE TREES OF NORTHEASTERN AMERICA

By CHARLES S. NEWHALL. With illustrations made from tracings of the leaves of the various trees. 8°. \$1.75.

New York G. P. PUTNAM'S SONS *London*

BOOKS FOR THE COUNTRY

WILD FLOWERS OF THE NORTHEASTERN STATES

Drawn and carefully described from life, without undue use of scientific nomenclature, by ELLEN MILLER and MARGARET C. WHITING. With 308 illustrations the size of life. 8°, *net*, \$3.00.

FIELD BOOK OF AMERICAN WILD FLOWERS

With a short description of their Character and Habits, a Concise Definition of their Colors, and References to the Insects which Assist in their Fertilization. By F. SCHUYLER MATHEWS, Member of the New England Botanical Club, and author of "Familiar Flowers of Field and Garden," "Familiar Trees and their Leaves," etc. 16°. With 24 Colored plates and 200 full-page illustrations in the text, *net*, \$1.75. By mail, \$1.85. Full leather, *net*, \$2.25.

NATURE STUDIES IN BERKSHIRE

By JOHN COLEMAN ADAMS. With 16 illustrations in photogravure from original photographs by Arthur Scott. 8°. Gilt top, in box, \$4.50.

LANDSCAPE GARDENING

Notes and Suggestions on Lawns and Lawn-Planting, Laying out and Arrangement of Country Places, Large and Small Parks, etc. By SAMUEL PARSONS, Jr., Ex-Superintendent of Parks, New York City. With nearly 200 illustrations. Large 8°. \$3.50.

LAWNS AND GARDENS

How to Beautify the Home Lot, the Pleasure Ground, and Garden. By N. JÖNSSON-ROSE, of the Department of Public Parks, New York City. With 172 plans and illustrations. Large 8°. Gilt top. \$3.50.

ORNAMENTAL SHRUBS

For Garden, Lawn, and Park Planting. With an Account of the Origin, Capabilities, and Adaptations of the Numerous Species and Varieties, Native and Foreign, and Especially of the New and Rare Sorts Suited to Cultivation in the United States. By LUCIUS D. DAVIS. With over 100 illustrations. 8°. \$3.50.

THE LEAF COLLECTOR'S HANDBOOK AND HERBARIUM

An aid in the preservation and in the classification of specimen leaves of the trees of Northeastern America. By CHARLES S. NEWHALL. Illustrated. 8°. \$2.00.

New York G. P. PUTNAM'S SONS *London*
